P.o. isosorbide and i.v. mannitol were compared for their effects on water, Na and K excretion in patients (21; 14 men, 7 women; 21-63 yr. old, with a mean age of 48) with cirrhosis of the liver and chronic or refractory fluid retention. The highest pretreatment urinary excretion of Na ranged from 1.0-140 mEq/day, with a mean of 33; that of K ranged from 28-117 mEq/day, with a mean of 50.7; and the mo. of duration of fluid retention ranged from 0.5-72, with a mean of 13.8 mo. Both isosorbide and mannitol produced water diuresis but did not produce significant Na and K losses when admin. alone. Both agents potentiated the Na excretion associated with spironolactone and hydrochlorothiazide. In patients excreting less than 6 mEq/day of Na, isosorbide produced significant Na excretion. P.o. isosorbide was studied for gastrointestinal, bone marrow, hepatic and renal toxicity; no significant adverse reaction was encountered in either the tests or clinical observations. P.o. isosorbide was of approx. the same effectiveness as i.v. mannitol and more convenient to admin.

10835 EFFECTS OF CHANGING PLASMA VOLUME, SERUM ALBUMIN CONCENTRATION, AND PLASMA OSMOLALITY ON RENAL FUNCTION IN CIRRHOSIS. (E.) McCloy, R. M. (Mayo Clin., Rochester, Minn.), W. P. Baldus, F. T. Maher and W. H. J. Summerskill. *Gastroenterology* 53(2):229-239, 1967.

Renal clearances of inulin and p-amino-hippuric acid, as well as of endogenous substances, were determined before and after single i.v. infusions of human serum albumin or hypertonic NaCl soln. in 22 patients (14 men, 8 women; 37-75 yr. old) with cirrhosis. Cirrhosis was associated with alcoholism in 13, and was of uncertain etiology in 9. Most of the patients had ascites and hypoalbuminemia; none had evidence of primary renal disease, but 7 had elevated blood urea conc. due to spontaneous impairment of renal function associated with liver failure. Single infusions of 50 g of albumin produced plasma vol. expansion and a mean increase in effective renal plasma flow (p-amino-hippuric acid clearance), but not in glomerular filtration rate (inulin clearance). No correlation existed between changes in plasma vol. and effective renal plasma flow; increases in effective renal plasma flow were limited to those patients with normal or only modestly impaired renal function, whereas those with the poorest renal function did not respond. After repeated albumin infusions, neither effective renal plasma flow nor glomerular filtration rate was altered despite maintenance of plasma vol. expansions and a significant rise in serum albumin conc. Hypertonic NaCl infusions produced an increase in plasma osmolality, but did not affect glomerular filtration rate or effective renal plasma flow. Urinary excretion of water and electrolytes was not significantly altered by infusions of either albumin or saline. These findings indicate that infusions of albumin or hypertonic NaCl are unlikely to be beneficial in the treatment of renal circulatory failure in cirrhosis, since neither substance produced improvement in patients with more severely impaired renal function.

10836 RENAL CONCENTRATING ABILITY IN CIRRHOSIS. I. CHANGES ASSOCIATED WITH THE CLINICAL STATUS AND COURSE OF THE DISEASE. (E.) Vaamonde, C. A. (U. New Mexico Sch. Med., Albuquerque), L. S. Vaamonde, H. J. Morosi, E. L. Klingler, Jr. and S. Papper. J. Lab. Clin. Med. 70(2):179-194, 1967.

Conc. ability was studied in patients with cirrhosis of the liver (9 men, 2 women; 28-64 yr. old; 10 with Laennec's cirrhosis and 1 with postnecrotic cirrhosis) at different stages of the disease and in chronically ill noncirrhotic control patients (9 men; 41-60 yr. old; these had such diseases as chronic pulmonary disease, multiple sclerosis, rheumatoid arthritis, chronic recurrent duodenal ulcer and postgastrectomy syndrome) under controlled dietary conditions. A significant reduction in max. urine conc. and in the rate of solute-free water reabsorption was found in the patients with cirrhosis. The noncirrhotic control patients had a normal conc. ability. The mechanism of the impaired conc. ability in cirrhosis was not clear. The data suggest that a decreasing delivery of Na to the distal site did not satisfactorily explain the conc. defect. However, because of the indirect methodology employed, it was difficult to formulate definite conclusions or to exclude some of the other alternative mechanisms which were suspected. Results obtained during the compensated and decompensated stages of the disease indicated that a relationship exists between the clinical status and course of the disease and the conc. ability of patients with cirrhosis. Whatever may be the mechanism of the impaired conc. ability in cirrhosis, it is reversible.

10837 INTRAVENOUS THERAPY OF MASSIVE ASCITES IN PATIENTS WITH CIRRHOSIS. I. SHORT TERM COMPARISON WITH DIURETIC TREATMENT. (E.) Vlahcevic, Z. R. (Lemuel Shattuck Hosp., Boston, Mass.), N. F. Adham, T. C. Chalmers, R. J. Clermont, E. W. Moore, H. Jick, G. W. Curtis and R. S. Morrison. Gastroenterology 53(2):211-219, 1967.

In a 2-part study, the effect of i.v. and diuret therapies, alone or in combination, on massive ascites, was studied in 18 patients with Laennec' cirrhosis. In Part 1, the 18 patients were divided into 3 groups: A) 6 patients who received autogenous i.v. ascitic fluid removed by paracentesis (4000 ml); B) 6 patients who received NaCl and albumin i.v. in amounts equivalent to that in the discarded ascitic fluid (4000 ml); and C) 6 patients received combinatio of potent diuretic drugs: 5 received varying conc. of hydrochlorothiazide (200 mg); prednisone (30 mg) and triamterene (200 mg) in planned sequences; and 1 received the bombination mercuhydrin (2 ml), spironolactone A (100 mg) and triamterene (200 mg), also in planned sequences. In Part 2 of the study, 3 different 1-day treatments were admin. at random as follows Treatment 1, diuretic therapy (mercuhydrin, 2 ml, or hydrochlorothiazide, 200 mg, and spironolactone A, 100 mg); Treatment 2, i.v. saline and albumin in amounts equivalent to discarded ascitic fluid, and no diuretics were given; and Treatment 3, a combination of the first 2 treatments, the diuretic being admin. so that its peak effect coincided with the i.v. therapy: mercuhydrin was admin. 1 hr. before i.v. infusion, and the combination of hydrochlorothiazide (200 mg) and spironolactone A (100 mg) was admin. p.o. as 1 dose 3 hr. before i.v. therapy. The i.v. infusion of ascitic fluid or albumin and saline during and after paracentesis resulted in moderate diuresis and natriuresis similar to that produced by diuretic therapy alone; there was no significant difference between ascites reinfusion and albumin-saline replacement of discarded ascitic fluid. Diuresis resulting from i.v. therapy appeared to be related to the expansion of effective circulating blood vol. with a subsequent rise in glomerular filtration rate, suppression of antidiuretic hormone activity and increase in free water clearance. Combination of diuretics with i.v. replacement therapy during paracentesis resulted in marked diuresis and natriuresis, and appeared to be an effective and relatively safe way of treating resistant ascites, particularly in patients with hyponatremia, defective renal function and azotemia.

10838 INTRAVENOUS THERAPY OF MASSIVE ASCITES IN PATIENTS WITH CIRRHOSIS. II. LONG TERM EFFECTS ON SURVIVAL AND FREQUENCY OF RENAL FAILURE. (E.) Clermont, R. J. (Lemuel Shattuck Hosp., Boston, Mass.), Z. R. Vlahcevic, T. C. Chalmers, N. F. Adham, G. W. Curtis and R. S. Morrison. Gastroenterology 53(2):220-228, 1967.

LIBRARY U. OF I. URBANA-CHAMPAIGN

y patients with cirrhosis and severe ascites
stratified into 3 groups according to the
ity of their liver diseases and ascites:
1, patients with severe ascites but no
aindication to diuretics; Group 2, patients
the same degree of ascites and 1 or more
aindications to diuretics; and Group 3,
nts similar to those of Group 2, but whose
output was definitely less than 500 ml/day.
nts were then randomly assigned to 1 of the
lowing modes of treatment: 1) conventional
py: conventional management of patients
cirrhosis and ascites according to their
ical status; included use of diuretics, but
never received i.v. therapy, except for
tment of hemorrhage; and Group 2, i.v.
py: no diuretics; abdominal paracentesis
reinfusion of ascitic fluid, or use of an
valent amount of 0.85% saline and 1-2%
min soln. The length of hospitalization after
mization was essentially the same for
entionally-treated and re-infused patients
in each group. In Group 1, ascites disappeared
r an av. of 8 wk. in patients conventionally-
ted and after 9 wk. in re-infused patients;
pheral edema regressed in 5 wk. among the
er and in 7 wk. among the latter. Patients
roup 1 showed a significant decrease of body
with time, but there was no treatment
erence; those in Group 2 failed to show a
ificant decrease in body wt. The occurrence
astrointestinal hemorrhage, expressed as the
er of bleeding episodes during the 10-wk.
od of observation, was essentially the same
each type of therapy, either within each
p or combining all groups. A significant
increase in blood urea nitrogen was found
roup 1 patients with no significant differ-
s between treatments; there was a tendency
rd a greater rise in the conventionally-
ted group. There were no significant changes
erum Na or albumin in Groups 1 and 2; serum
id increase significantly in i.v.-treated
p 3 patients. Survival of patients was
6 mo.) 84±5.1% for Group 1, 33±11.1% for
p 2 and 0% for Group 3, indicating a statisti-
y significant difference between groups. In
p 1, 56% of the patients were alive 36 mo.
r randomization, whereas 50% survival was 7
and 2.5 wk. for Groups 2 and 3, resp. The 2
erent treatments had no demonstrable influence
urvival. Four major complications contribut-
to death included renal failure, hemorrhage,
ction and progressive encephalopathy; renal
ure occurred in 34 of 48 dying patients (71%),
no difference between conventionally-
ted and i.v.-treated patients. Hemorrhagic,
ctious or encephalopathic complications were
less important, and represented only 19, 6
2% of the deaths, resp. This study
hasizes the importance of the controlled clini-
trial in the final evaluation of a physiologi-
ly rational and acutely effective therapy. The
rtance of randomization was demonstrated here
he marked differences in survival when patients
classified according to clinical criteria be-
therapy and the lack of appreciable differen-
when randomly assigned treatments are compared.

10839 APPLICATION OF A NEW METHOD OF HEPATOBILIARY SULFOBROMOPHTHALEIN CLEARANCE TO THE STUDY OF HEPATIC FUNCTION IN PATIENTS WITH CIRRHOSIS. (It.) Pieragnoli, E. (G. Ceccarini Hosp., Riccione, Italy), P. Pasini and G. Baldacci. Quad. Sclavo Diagn. 3(1):72-82, 1967.

The authors have devised a new method for the study of liver function based on Tura's method for the mathematical analysis of the kinetics of BSP excretion using an electronic calculator. Since the previous method had permitted the analysis of Segment II (representing the return of BSP from the liver back to the plasma, according to the author) not as an isolated entity but as part of a mathematical evaluation of both segments, the authors applied this method to 21 patients with cirrhosis (diagnosed by clinical examination and laboratory tests), thus obtaining an index of hepatic function as well as a Cholostatic Index. In these patients, a decrease in the Hepatic Function Index was observed ranging from 62 to 82, while the I.C. was generally increased ranging from 2 to 3.8. In order to facilitate understanding of the new method, the authors illustrate the various steps and calculations using data from a sample case. Commercial sodium tetrabromophenolsulfophthaleinate (800 mg) was admin. i.v. to the patient, fasted from the evening before; from a vein in the other arm, blood samples were obtained under basal conditions and 5, 10, 15, 25, 30, 45, 60, 90, and 120 min. after admin. of the dye. Optic density values were obtained spectrophotometrically and plotted on semilogarithmic paper, from which the plasma conc. curve of the dye was subsequently calculated. Further calculations according to the Tura formula produced Hepatic Function Index and Cholostatic Index values (82.3% and 2, 7, resp., in the sample case). The advantages of the new method over previous methods is the possibility of its application to patients with jaundice (thus permitting a distribution between parenchymal and cholostatic damage) as well as its prognostic value.

10840 ASCITES IN CIRRHOSIS. RELATIVE IMPORTANCE OF PORTAL HYPERTENSION AND HYPOALBUMINEMIA. (E.) Castell, D. O. (U.S. Naval Hosp., Great Lakes, Ill.). Amer. J. Dig. Dis. 12(9):916-922, 1967.

The relation of wedged hepatic vein pressure and serum albumin conc. to ascites in 20 patients with portal (alcoholic) or postnecrotic cirrhosis confirmed by needle biopsy of the liver was studied; there were 6 patients with ascites and 14 without diagnosable ascites. The normal range for serum albumin conc. was considered to be 3.8-4.6 g/100 ml, and portal hypertension was defined as a wedged hepatic venous pressure greater than 13 mm Hg. In 6 patients with ascites, all had elevated portal pressure (mean 20.3 mm Hg, with a range of 15-24); the mean serum albumin conc. was 2.9 g/100 ml (with a range of 2.2-3.5). Of 14 without ascites, mean hepatic wedge pressure was 14.4 (with a range of 8-25 mm Hg), and mean serum albumin conc. was 3.6 g/100 ml (with a range of 3.1-5.5 g/100 ml); increased portal pressure was present in 57% (8 of 14) of these patients. The patients with ascites all had wedge pressures greater than the mean pressure of the non-ascites group, and all had serum albumin levels less than the mean of the nonascites group. In the nonascites group, 2 patients had hepatic wedge pressures which exceeded the mean pressure of the ascites group, and all of the patients without ascites had serum albumin levels greater than the mean level of the ascites group. Ascites did not appear in any case with albumin greater than 3.5 g/100 ml, and it was present in all cases with albumin less than 3.1 g/100 ml. Statistical evaluation of the data revealed a much greater correlation of ascites to serum albumin than to wedged hepatic venous pressure. Application of the same analytic methods to a previous report on a larger group of cirrhotic patients revealed similar findings. It is suggested that hypoalbuminemia is of much greater importance than portal hypertension in the pathogenesis of ascites in patients with cirrhosis of the liver.

10841 SECONDARY ALDOSTERONISM IN PATIENTS WITH HEPATIC CIRRHOSIS AND ALDOSTERONE EXCRETION AFTER VASCULAR ANASTOMOSES. (Rus.) Sprintsson, R. G. (Leningrad Med., Sanit. Hyg. Med. Inst., USSR). Vestn. Khir. Grekov 97(10): 15-18, 1966.

Eight males and 2 females (17-40 yr. old) with liver cirrhosis and portal hypertension and with establishment of veno-venous anastomosis exhibited increased aldosterone excretion (indicated by its hypersecretion by adrenal glands and by disturbance of inactivation of liver function), and symptoms of secondary aldosteronism aggrevated by and appearing after surgery. Aldosterone excretion was increased in all cases and some patients developed ascites or edema. In controls (5 healthy males and 5 healthy females, age 20-60 yr.) daily aldosterone excretion in the urine varied between 1-10 μg (av. 6.8). Most of the patients showed hypotonia, 6 had postnecrotic, 3 portal and 1 postnecrotic-portal liver cirrhosis in the compensation or subcompensation phase. Four patients showed ascites before surgery; it was transitory in some and the daily aldosterone excretion by urine varied from 18-45 μg (av. 27.5). The postsurgical course varied, and severity of conditions and lethal outcome were determined by preservation of hepatic parenchyma and postsurgical complications such as: Thrombosis of established vascular anastomosis and hemorrhage from varicose veins of esophagus and stomach. Aldosterone content in daily urine varied from 25-65 μg (av. 40.2). Aldosterone excretion was especially high in the patients with severe postsurgical period and lethal outcome; as a rule they also had pronounced presurgical aldosteronism. Postsurgical aldosteronism was clinically more evident in th form of edema and ascites.

10842 CIRRHOSIS AND JAUNDICE. (Rum.) Pave I., S. Câmpeanu, C. Dumitrescu and H. Bonaparte. Med. Intern. (Bucur.) 19(2):157-169 1967.

The conditions favoring the presence of jaundic in patients with cirrhosis are decreased hemoglobin production and protein deficiency while those combating the disease are permeability of the biliary ducts and regeneration of liver cells. Admin. of 17-methyltestosterone to 14 noncirrhotic patients decreased endogenous bilirubin clearance, while in 3 cirrhotic patients plasma bilirubin clearance remained unchanged. Duodenal catheterization for cirrhosis reveals that the permeability of the intra- and extrahepatic ducts remains normal. In 6 of 7 cirrhotic patients, RBC incorporation of ^{59}Fe decreased enough to suggest a decrease of hemoglobin production; the same phenomenon was prov indirectly by measuring endogenous Fe clearance in cases with nicotinic acid induced hypersideremia. Hemolysis was greatly increased in of 10 cirrhotic patients and endogenous bilirubin was increased in 53 with cirrhosis. Indu hypersideremia and endogenous Fe clearance was increased (as compared to controls) during the first 120 min. following treatment with nicotin acid and the elimination of the circulating endogenous bilirubin was delayed. Admin. of carbachol decreased BSP elimination in 12 cirrhotic patients. In 3 with cirrhotics, jaundice was treated by splenectomy (responsible fo increased hemolysis and hyperbilirubinemia) in 33%, adequate diet and rest in 33%, and diet, rest, and abstinence from alcohol in 33%. In a fourth patient with chronic jaundice (without cirrhosis) and hypertonic Oddi's sphincter who did not respond to splenectomy, bile drainage b duodenal catheter produced complete remission for at least 3 yr.

10843 FUNCTIONS OF THE SPLEEN IN CHRONIC HEPATITIS AND IN CIRRHOSIS. (Fr.) Gheorghesco, B. (Ctr. Gastroent., Bucharest), G. Jovin, E. Merculiev, E. Timis and D. Mardale. Rev. Roum. Med. Int. 3(6):451-457, 1966.

The half-life of RBC labeled with ^{51}Cr was determined in 104 patients with chronic hepatiti or cirrhosis, 33% of whom had splenomegaly or signs of hypersplenism. Scintigraphy with colloidal radioactive Au (particle diameter 40-50 mμ) was done in more than 70 subjects. Controls comprised 8 normal persons. The av. half-life of the labeled RBC was 27 days for controls and 18.1 for those with chronic inflammatory liver disease. Related to this was the image of the spleen appearing in the scintigraphs of those with inflammatory liver diseases but not the image of persons with normal livers. The sequestration of ^{51}Cr-labeled

in the spleen was augmented by inflammatory
er disease which also increased the accmula-
n of colloidal Au in that organ. RBC and
loidal Au were also increased in the liver
elf but not necessarily in direct correlation
h the spleen. Possible common mechanisms for
gocytosis of colloidal Au and retention of
are discussed.

44 THE NEPHROMEGALY OF CHRONIC ALCOHOLICS
WITH LIVER DISEASE. (E.) Laube, H.
ston City Hosp., Mass.), H. T. Norris and
L. Robbins. Arch. Path. (Chicago) 84(3):
-294, 1967.

ney wt. of 89 consecutive cases of chronic
oholics were compared with the degree of their
er involvement, with cases of non-alcoholic
rhosis, and several control groups. The
lowing groups were studied: 1) 17 cases,
nical history of alcoholism, no liver
hology; 2) 17 cases, compensated fatty
ritional cirrhosis; 3) 40 cases, decompensated
ty nutritional cirrhosis; 4) 15 cases, chronic
oholics, fatty livers and varying stages of
rosis, but no cirrhosis; 5) 30 cases, non-
oholic cirrhosis; 6) 30 cases, no history of
oholism and immediate death; and 7) 130
es, patients who died in the hospital of
elated diseases and with no history of
oholism. A significant nephromegaly was pre-
t in all cases of cirrhosis, regardless of
se; this ranged from a 16% increase in non-
oholic cirrhotics to a 31% increase in those
h decompensated fatty nutritional cirrhosis.
degree of nephromegaly was directly propor-
nal to the amount of hepatomegaly. Among
onic alcoholics, the greatest nephromegaly
associated with fatty metamorphosis of the
er, without cirrhosis.. Assay of renal tissue
id, protein, lipid and carbohydrate revealed
accumulation of any 1 these tissue components.
is concluded that nephromegaly was the result
added tissue mass, best explained on the
is of cellular hypertrophy and hyperplasia.

45 EXPERIMENTAL HEPATOCEREBRAL DISEASE.
ASTROCYTIC CHANGES IN THE GLOBUS
LIDUS OF RATS WITH CARBON TETRACHLORIDE
UCED CIRRHOSIS. (E.) Hasson, J. (Washington
Sch. Med., St. Louis, Mo.) and R. W. Leech.
h. Path. (Chicago) 84(3):286-289, 1967.

Alzheimer glia cell, an altered astrocyte
racterized by a striking increase in the size
the nucleus associated with pleomorphism, is
racteristically observed in man in the basal
glia and other parts of the brain in chronic
er disease. In an effort to produce these
nges experimentally, liver cirrhosis was pro-
ed in male Sprague-Dawley rats with CCl_4
ml/kg, admin. 2 times/wk. for 5 wk., for a
al of 10 doses) admin. by gastric intubation.
ssical Alzheimer glia cell changes were not
erved in the globus pallidus of the cirrhotic
rats, but a definite astrocytic response was produced. A significant increase in the mean astrocytic nuclear size in the globus pallidus of cirrhotic rats and shown, as compared to con trol animals. The mean astrocytic nuclear size in 14 cirrhotic rats was 7.04μ±1.30 μ, compared to 6.71 μ± 1.21 μ in 17 control rats. Mean body, liver and brain wt. in 13 cirrhotic rats were 220.2 ± 20.3 g, 12.35 ± 1.81 g and 183.9 ± 5.0 g, resp., compared to 312.0 ± 30.2, 11.16 ± 1.54 and 199.6 ± 7.6, resp., in 17 control rats.

10854 TRANSHEPATIC DRAINAGE OF THE BILIARY PATHWAYS. (Cz.) Jarošek, H. (Charles U., Prague). Cesk. Gastroent. Vyz. 20(8):547-549, 1966.

Drainage of the biliary pathways is indicated in those cases when primary suture of the common bile duct cannot be performed. The usually applied T-drain has several disadvantages. An improved method of transhepatic drainage combining the advantages of drainage with those of primary suture is described. Using a specially adjusted surgical instrument, penetration was performed from the lumen of the biliary pathways to the convexity of the liver; in the channel formed a silk thread was introduced. A thin polyethylene drain was attached to the end of the thread emerging from the choledochotomy and, by pulling the thread back, the drain was first introduced into the biliary pathways. It was then pulled further through the perforations in the liver and the abdominal wall and attached to the skin. Fixation of the drain to the convexity of the liver was unnecessary. The incision in the common bile duct could be closed with this type of drain. The drain was applied in 25 cases without any complications. Obstructive jaundice accompanied by pronounced disturbance of hemocoagulation equilibrium represents the only contraindication of application of the type of drainage.

10855 SERUM ALBUMIN RESERVE PSP DYE BINDING CAPACITY IN INFANTS WITH KERNICTERUS. (E.) Lucey, J. F. (Queen Anna-Maria Inst. Child Health, Athens), T. Valaes and S. A. Doxiadis. Pediatrics 39(6):876-883, 1967.

Evidence would indicate that albumin exerts a protective action against the toxic effects of bilirubin. The capacity of serum to bind the dye, phenolsulfonphthalein, is related to the conc. of serum bilirubin and other substances which are bound to albumin. A phenolsulfonphthalein binding capacity of over 100 μg/ml serum is considered adequate, indicating that a newborn is safe from bilirubin encephalopathy regardless of the conc. of serum bilirubin. A binding capacity of less than 50 μg/ml is an indication for immediate exchange transfusion. The binding capacity of phenolsulfonphthalein was studied in 93 newborns with total serum bilirubin conc. ranging from 20-52 mg/100 ml. The test was found to be neither reliable nor useful as a screening device in deciding the possibility of kernicterus.

10856 EXPERIMENTAL REPLACEMENT OF THE COMMON BILE DUCT BY MEANS OF A CRIMPED TEFLON TUBE USING THE DUODENAL WALL. I. OPERATIVE TECHNIC. (It.) Rigotti, E. (U. Turin, Italy), M. Dellepiane and R. De Matteis. Arch. Sci. Med. (Torino) 122(6):467-478, 1966.

The authors describe a new technic for the surgical replacement of a portion of the common bile duct using a crimped Teflon tube (diameter 3 mm). The technic had previously been used successfully by the authors for surgical ureter replacement. Ten dogs were subjected to the ne technic in the present report. The prosthesis, corrugated at its outer surface to allow easy bending without reducing the caliber, is passed through a tunnel created within the duodenal wall. Within the prosthesis, a silicon rubber tube is passed which allows passage of bile int the intestine. The rubber tube is kept in plac for 20-25 days (the time needed for organizati of the prosthesis to take place) and then remov The proximal end of the common bile duct is inserted into the lumen of the prosthesis (past the cranial limit of the tunnel) and the outer surface of the common bile duct is then sutured to the proximal end of the prosthesis. The distal portion of the prosthesis is pulled down an inserted into the intramural portion of the com bile duct wall. The technic offers 3 important advantages: (1) the silicon rubber tube permit adequate drainage of bile without danger of obliteration of the newly-formed duct by precipitation of cholesterol and bile pigments; (2 the creation of a submucosal tunnel accelerates the formation of connective tissue and subseque organization of the prosthesis; (3) the use of crimped tube eliminates the danger of bending, frequent cause of bile salt precipitation. The operation was well tolerated and results of laboratory tests were encouraging.

10857 EXPERIMANTAL REPLACEMENT OF THE COMMO BILE DUCT BY MEANS OF A CRIMPED TEFLO TUBE USING THE DUODENAL WALL. II. CLINICAL AN FUNCTIONAL RESULTS. (It.) Dellepiane, M. (U. Turin, Italy), E. Rigotti and R. De Matteis. Arch. Sci. Med. (Torino) 122(6):479-492, 1966.

Results of the experimental replacement of a portion of the common bile duct by means of a crimped Teflon tube are reported in 10 dogs. Death occurred in 3 dogs: Dog A died during surgery, probably from excessive anesthetic (sodium pentothal) dosage or because of intolera to the anesthetic; Dog B died 5 days after surge from choleperitoneum due to dehiscence at the proximal anastomosis site; Dog F died 68 days after surgery from perforated gastric ulcer. In the 7 surviving dogs, determination of serum bilirubin levels and of urinary and fecal bile pigment content, as well as X-ray examination of the biliary tract, were performed 10, 30, 60, 90, and 120 days after surgery; 4 dogs were sacrificed at days 30, 60, 90, and 120, resp., and histological examination of the liver was performed. Serum bilirubin levels were slightly increased (4.3 mg% in 1 animal) at day 10 after surgery, but levels returned to normal by day 30 Urinary bile pigment tests were positive in s at day 10; by day 30, the tests were ive in all but 1 dog. Feces pigmentation ormal in 6 dogs; the feces of dog H were ic between days 15 and 27 but returned rmal afterwards. X-rays revealed pervious- of the prosthesis in all animals; some ation was observed in the tract immediately the prosthesis, but no gallbladder dilata- was seen. Histological studies showed no ation of the hepatic parenchyma. Although umber of animals used is small, the rs feel that results are encouraging and further experimental studies.

EXPERIMENTAL REPLACEMENT OF THE COMMON BILE DUCT BY MEANS OF A ED TEFLON TUBE USING THE DUODENAL WALL. EARLY MORPHOLOGICAL RESULTS. (It.) eis, R. (U. Turin, Italy) E. Rigotti and lepiane. Arch. Sci. Med. (Torino) 122(6): 5, 1966.

copic and microscopic studies were con- in 4 of 10 dogs sacrificed 30, 60, 90, 0 days, resp., after surgical replacement ortion of the common bile duct by means rimped Teflon tube. Gross examination ed the presence of adhesions of varying and consistency between the omentum, al wall, gallbladder, and inferior surface liver. The liver and gallbladder were with respect to appearance, vol., and tency. Squeezing of the gallbladder ed free passage of liquid, normally-colored nto the duodenum. The portion of the common uct above the prosthesis was difficult tinguish and was moderately dilated in nimals. The duodenal wall at the level newly-formed common bile duct presented osal or serosal alterations, nor were flammatory, dystrophic, or cicatricial s present. Duodenal transit was normal. udinal section of the tunnel created the duodenal wall revealed firm attachment prosthesis within the wall, and a solid of connective tissue around the prosthesis. ogical examination revealed a mucosal composed of columnar, muciparous, epithelium andular structures, and a layer of fibrous tive tissue with infiltration of inflam- elements. The submucosal layer contained band of granulation tissue around the The muscular layer was somewhat narrower. dog sacrificed at day 120, the common ct presented a normal lumen lined with a of columnar cells resting on a band of connective tissue. The authors feel en though the observation period is short, formity of results suggests a certain of optimism with regard to this technic on bile duct replacement.

THE DYNAMICS OF THE MAIN BILIARY DUCT AND THE MECHANISM OF THE BILIOPANCRE- FLUX. (E.) Pinotti, H. W. (U. Sao Paulo, Brazil), O. M. DeSousa, J. B. Parolari, V. P. Conte, A. Raia and A. C. Netto. Amer. J. Dig. Dis. 12(9):878-890, 1967.

The dynamics of the main biliary duct and the mechanism of biliopancreatic reflux were studied by means of cinefluorography and electromanometry in 11 patients (2 men, 9 women; 21-60 yr. old, with an av. of 35 yr.) undergoing cholecystectomy because of chronic calculous cholecystitis; 3 also had choledocholithiasis and were treated surgically. Contrast inj. were performed using 3 different types of pressure: 1) residual pressure; 2) passage pressure; and 3) gradual hyperpressure. The patients were distributed in 2 groups: 1) in 7 patients, the kinetic study of the biliary system was made both before and after a fatty meal (ingestion of egg yolks and 100 ml of milk); and 2) 4 patients, subjected to a pharmacodynamic study of the bile ducts, using i.m. inj. of 0.01 g morphine; inhalation of amyl nitrite and i.v. inj. of 0.5 mg of atropine. The terminal portion of the bile duct (the bile-duct sphincter) and the musculature of the ampulla were found to contract together, and a functional autonomy of the sphincter of Oddi was rarely observed. A choledochoduodenal synergy was noted in each case, and spasm of Oddi's sphincter was synchronous with duodenal spasm. Pancreatic reflux occurred with pressure levels varying from 12-50 cm of saline soln.; after a fatty meal, the reflux could be obtained only with high pressures; it was concluded that a fatty meal may hinder the reflux in the pancreatic duct in subjects without biliary disease. No pancreatic reflux was obtained by using drugs; morphine caused total spasm of Oddi components; even a continuous perfusion under pressure above the residual level failed to bring about a reflux into Wirsung's duct, owing to hypertony of the sphincter complex.

10860 OBSERVATIONS ON SINGLE SECTION OF THE SPHINCTER OF ODDI. (E.) Braasch, J. W. (Lahey Clin. Found., Boston, Mass.) and J. C. McCann, Jr. Surg. Gynec. Obstet. 125(2):355-358, 1967.

A heterogeneous group of 231 patients with a diagnosis of stenosis, stricture or spasm of the ampulla of Vater was studied to assess certain features of transduodenal sphincterotomy. For a group of 173 patients, the mortality rate was 4.6% after choledochostomy and transduodenal sphincterotomy with or without a variety of other procedures; in a group who underwent choledochostomy only and transduodenal sphincterotomy, the mortality rate was 5.6%. Of 8 fatal complications, infection was responsible for 3 and pancreatitis for 2 of the deaths. In 15 patients re-exploration at varying times after transduodenal sphincterotomy showed maintenance of the large lumen through the sphincter in almost all cases. No consistent change occurred in duct emptying produced by sphincterotomy as recorded by time-density measurements at cholangiography, but 4 of 5 ducts that were greater than

14 mm in diameter preoperatively were markedly reduced in size postoperatively. In those patients without stones or pancreatitis, transduodenal sphincterotomy produced only 39% satisfactory results in relief of pain. If only large ducts were observed preoperatively, 53% of the patients had a satisfactory result.

10861 THE SITES TO WHICH PAIN IS REFERRED FROM THE COMMON BILE-DUCT IN MAN AND ITS IMPLICATION FOR THE THEORY OF REFERRED PAIN. (E.) Doran, F. S. A. (Mid-Worcestershire Hosp., Bromsgrove & Kidderminster, England). Brit. J. Surg. 54(7):599-606, 1967.

In 56 patients (49 women, 7 men), a small Foley catheter was used to drain the common bile duct after cholecystectomy; on the twelfth postoperative day, when the patient was completely conscious, convalescent and cooperative, the balloon of the catheter was distended and the sites of referred pain ensuing from this procedure were recorded. Five patterns emerged. In 18, pain was referred to the epigastrium and the area about the xiphoid process in the trunk midline; in 1 additional patient it was located slightly lower, in the upper unbilical area and in 1 it was confined to the navel. In 10, pain was referred to the right costal margin and the right hypochondrium. In 6, it was found in the epigastrium and xiphoid area in the midline and radiated through to the back. In 5, it was found only in the back between the shoulder blades and across the lumbodorsal region. In 4, pain was confined to the back, but was unilateral; 1 of these 4 patients experienced the pain on the opposite side of the back by the lower angle of the left scapula. In 11 patients, no pain was experienced anywhere, in spite of considerable tension in the balloon. The implication of this study for the theory of referred pain is discussed in detail. Ample evidence exists that the first stage of the afferent pathway from the biliary tree to the brain lies in the splanchnic nerves and the corresponding filaments of the abdominal sympathetic networks, and that usually the innervation is bilateral. The variations in the sites to which pain is referred from the common bile duct show that, embryologically, the position of the common duct, remote from the neural crest, greatly reduces its ability to attract pain afferents to it. The different sites to which pain is referred from the common duct is contradictory to the notion of true visceral pain as a pain occurring in a viscus. This series also demonstrates that pain confined to the right upper abdominal quadrant is not, by itself, evidence that local peritonitis has developed. Finally, the fact that distention of the common bile duct often produces pain in the back disposes of the widespread belief that this is evidence of the involvement of the posterior wall of the abdominal cavity by the disease process. The physiological mechanism of referred pain depends on nothing more complex than the termination of pain afferents from t viscera, the deep somatic structures, and the skin, on a common pool of connector neurons in the same segment of the spinal cord; this theory requires only the basic physiological process of summation to make it explain the observed clinical facts. The exact site to which a pain of visceral origin is referred is almost certainly finall determined by the higher centers in the brain

10862 A COMBINED METHOD FOR DIAGNOSIS I MALIGNANT JAUNDICE. (E.) Sato, (Tohoku U., Sendai, Japan), G. Kakizaki, Y. Saito, T. Maki and K. Koyama. Arch. Surg. (Chicago) 95(2):207-216, 1967.

A combined diagnostic method, consisting of the pancreatic exocrine function test, 2) percutaneous transhepatic cholangiography, 3 splenoportography, and 4) selective arteriog was used in 46 cases of malignant jaundice d to cancer of the pancreas and the biliary system. There were 31 cases of periampullar cancer (which in this study was defined so a include cancer of the head of the pancreas (cases), cancer of the intrapancreatic bile d (12 cases) and cancer of the papilla of Vate (7 cases)), 11 cases of cancer of the extrap creatic bile duct and 4 cases of cancer of t gallbladder. With regard to location of obstruction, 25 (81%) of 31 cases of periampul carcinoma were correctly diagnosed preoperat among which the accuracy was 67% in 12 cases of carcinoma of the intrapancreatic bile ducts. Diagnosis was accurate in all 6 case of carcinoma of the extrapancreatic bile duc but it was lowest (50%) in 4 cases of cancer of the gallbladder. Of the 46 cases of cancer of the biliary system, 38 (83%) were diagnosed accurately. With regard to resect bility, 26 of 27 (96%) were predicted corre in the case of periampullary carcinoma, whil 78% were accurately preducted in 9 cases of carcinoma of the extrapancreatic bile ducts. Of 3 cases of cancer of the gallbladder, 2 were predicted accurately before laparotomy. In total, the diagnostic accuracy was as high as 90% (35 of 39) with regard to resec ity in carcinoma of the pancreas and the bi tract.

10863 CINE-CHOLANGIOMANOMETRY: PHYSIOL OBSERVATIONS. (E.) Beneventano T. C. (Montefiore Hosp., New York, N. Y.), H. G. Jacobson, E. S. Hurwitt and C. J. Sch Amer. J. Roentgen. 100(3):673-679, 1967.

Among 15 patients referred for postoperativ cinecholangiography, with film strips deriv at graded increments of intracholedochal pr (+5 cm contrast medium, repeated to a max. of 50 cm sodium diatrizoate), contractions the common bile duct originated only in the vaterian segment, from which they were tran

lively. Involved was a rhythmic process of
xation and contraction, arising in the distal
ent and apparently representing diastolic
systolic phases of choledochal sphincter
vity. During the systolic phase, the
al end of the duct was sufficiently
racted to prevent flow of the contrast
um into the duodenum. The diastolic
e, in turn, began with the opening of
contracted segment, extended to the rest
he duct through a period of progressive
xation, and terminated with the start
new systolic contraction. The duration
ystole at baseline passage pressure ranged
0.5-4.3 sec.; that of diastole, from
5.3 sec. Both phases were lengthened
eciably in response to increase of pressure
in the duct. No patient experienced pain
aseline passage pressure, which was highly
vidualized; all experienced pain when
aductal pressure was increased by 13-26
ater above the individual baseline: i.e.,
-58 cm water (mean - 39 cm). Seven of 15
ects experienced reflux of the contrast
m into the pancreatic duct, occurring in
nstances below the individual's pressure-pain
hold level and thus appearing to indicate
pain did not result from filling or
ntion of the pancreatic duct in itself,
ugh it was relieved immediately when the
was permitted to empty. There was no
nce of pancreatitis resulting from such
eatic duct reflux.

INTELLIGENCE OF CHILDREN WHOSE
MOTHERS HAVE BILIARY TRACT DISEASE.
Churchill, J. A. (Wayne State U., Detroit,
), M. A. Ayers and D. F. Caldwell. J.A.M.A.
):482-484, 1967.

ntelligence of children whose mothers
olecystectomies for cholelithiasis, with
thout cholecystitis, was compared to the
ligence of control children. The number
ildren tested was 39, since some mothers had
dren enrolled in the project. The
er Intelligence Scale for children was
ychometric test used. The control group
oup with maternal biliary-tract disease
mean IQ of 113.1 and 100.6, resp. Within
oup with maternal biliary-tract disease
elation between severity of maternal
s and IQ of the child was found. It is
ded that maternal biliary-tract disease
terfere with fetal brain growth resulting
manent limitation of intellectual develop-
It is speculated that the availability
oleic acid for fetal brain development
be decreased in pregnant women who have
y tract disease.

INJURY TO THE SPHINCTER OF ODDI IN
THE COURSE OF GASTRIC AND DUODENAL
Y. (E.) White, T. T. (U. Washington,
e), E. R. Sanderson and A. Morgan.
J. Surg. 114(2):247-253, 1967.

Six further cases of operative injuries to the ampulla of Vater are described, in addition to the 65 injuries of this type which have been previously reported in the literature; 69 of 71 injuries occurred during gastric resection for chronic duodenal ulcer. One of the 6 cases described occurred during excision of a large duodenal diverticulum and the other occurred during excision of a duodenal polyp. Usually the ulcer which necessitated gastrectomy was postbulbar or in the second part of the duodenum, causing considerable deformity. In only 9 of 69 cases of ulcer was the ampulla separated deliberately; in 13 cases, the surgeon was attempting to reach distal to the ulcer by freeing the duodenum from the pancreas from below upwards. Another cause of this injury was overenthusiastic mobilization of the duodenum by the Kocher maneuver before dealing with the duodenal stump. Most of the cases were recognized at the time of accidental injury; only 14 of 62 passed unrecognized. In cases in which the injury was accidental, 8 patients of a total of 61 died. Deliberate separation and reimplantation resulted in no deaths in 10 cases. A method of duodenal advancement and anastomosis to the area of the ampulla together with drainage by transduodenal catheters of 2 to 4 F polyvinyl tubing in each duct is the most acceptable operative repair in these cases. Vagotomy and pyloroplasty is a preferred method of avoiding this injury.

10866 THE EXTERNAL DRAINAGE OF BILE
PASSAGES AFTER PAPILLOTOMY.
(Rus.) Gausman, B. Ia. (Kemerovo Med. Inst.,
USSR). Vestn. Khir. Grekov 98(4):52-54, 1967.

External drainage of bile passage following transduodenal papillotomy was used in 3 female patients (2 are 37, 1 is 66 yr. old) with stones in the terminal part of the common bile duct, which could not be removed by supraduodenal incision. One end of a polychlorvinyl tube (diameter 5 mm) was introduced into the hepatic duct through the resected papilla, above the location of the common bile duct opening; then a thick gastric sound was introduced through the mouth, drawn into the duodenal incision and attached to the end of the polychlorvinyl tube and extricated back through the mouth; sutures on the common bile duct and duodenum were established and after extubation the sound was transferred from the oral cavity through the lower meatus nasi out. This method has the following advantages: enables suture on the common bile duct; decreases danger of peritonitis; prevents development of postsurgical pancreatitis and intestinal paresis; decreases danger of separation of the sutures of the duodenal wall; drainage is controllable, deprived of deficiencies of common internal drainage; and the postsurgical period passes relatively easily, despite severe surgery.

10867 UROCHOLECYSTOKININ IN DIAGNOSIS OF EXTRAHEPATIC BILIARY DUCTS. (Rus.) Popova, E. A. (1st Moscow Sechenov Med. Inst.), A. A. Zychkova, A. E. Fioletova and T. V. Gol'tiakova. Ter. Arkh. 39(3):37-40, 1967.

Fifty persons, 16 with chronic cholecystitis, 12- gallbladder dyskinesia, 3- postcholecystectomy syndrome, and 4 without pain syndrome were observed 2-5 yr. after gallbladder removal; 15 controls were also studied. Nine of 16 with chronic cholecystitis showed a decrease in intensity of gallbladder shadow at contrast roentgenography and in 5 there were concrements; in 7 the shadow was good with 4 of the 7 showing concrements. Eight of 12 with gallbladder dyskinesia showed a hypotonic form while in 4 others the gallbladder showed no roentgenological changes. Urocholecystokinin content (determined by Svatoš method) in the urine, taken 1.5 hr. after admin. of irritants ($MgSO_4$ or sunflower oil), was determined in guinea pigs. In 7 patients with chronic cholecystitis with preserved conc. function of gallbladder, urocholecystokinin content (on empty stomach and after admin. of irritants) was normal, e.g., 0.08-0.1 and 0.14-0.16 dog U, resp., while in 9 patients with disturbed conc. function of gallbladder it decreased, e.g., 0.02-0.04 and 0.08-0.12 dog U, resp. In 12 patients with dyskinesia and 3 with postcholecystectomy syndrome, resp., values were 0.15-0.20 and 0.28-0.40 dog U, e.g., urocholecystokinin content was increased; and in 4 patients without pain sensation it decreased, e.g, 0.04-0.08 and 0.02-0.04 dog U. Determination of urocholecystokinin in patients with different gallbladder pathology showed definite regularity and could be an additional test in diagnosing gallbladder diseases.

10868 THE INFLUENCE OF DIHYDROERGOTAMINE ON CERTAIN HEPATIC FUNCTIONS IN MAN. (Fr.) Charbonnier, A. (Cochin Hosp., Paris) and M. Cachin. Sem. Hop. Paris 43(25):1673-1684, 1967.

The possible effects of dihydroergotamine upon the contraction of the gallbladder, the secretion of bile, and BSP clearance were investigated. Dihydroergotamine had no cholecystokinetic effect; the wave of contraction sometimes observed in cholecystography at the base of the gallbladder was never associated with the passage of bile from the gallbladder into the duodenum. Dihydroergotamine caused a brief decrease in bile flow followed by an increase; there was no effect upon the composition of the bile. It is suggested that this effect is due to the action of this preparation upon the blood vessels. Admin. of 2 mg i.v. immediately before the inj. of BSP seemed to have an effect on the clearance of the dye, usually accelerating it. Dihydroergotamine also interfers with galactose tolerance tests.

10869 TREATMENT OF THE COMMON BILE DUCT
PANCREATITIS. (E.) White, T. T.
(U. Washington Sch. Med., Seattle) and J. E.
Murat. Amer. Surg. 33(7):524-528, 1967.

The following types of operations were perfo
on 182 of 733 cases with pancreatitis: 66 h
common duct explorations only, 80 had sphinc
tomies, 16 choledochoenterostomies, 9 long
arm T-tubes and 8 dilatations of the sphinct
of Oddi as well as common duct exploration.
these 182 patients, 140 were classified as h
ing acute pancreatitis and among these 101 h
stones in the common bile duct. Of those wi
acute pancreatitis, 27 were jaundiced, 17 we
alcoholic and 11 had a duodenal ulcer. The
remaining patients were considered to have
chronic pancreatitis indicating permanent
change in the pancreas: a third of these ha
intrapancreatic calcification, nearly half w
alcoholics and 11 had associated gallstones.
In addition, there were 22 patients with pos
operative pancreatitis of whom 18 had gallst
and nearly half had common bile duct stones.
In the total group of 204 patients 22 were
treated by 7 mm or more dilatation of the
sphincter of Oddi: 10 died. Also in this s
a long-arm T-tube (size 12F or greater) was
installed in 14 patients, of whom 6 subsequ
died while a number of others had difficult
postoperative courses. In contrast common
duct exploration with probes up to 5 mm pro
relatively little morbidity. In conclusion
choledochoenterostomy is the preferred meth
drainage where there is a long stricture of
distal common bile duct, whereas sphinctero
or sphincteroplasty is preferred in treatin
common bile duct when the sphincter of Oddi
localized obstruction.

10906 SURGICAL PROBLEMS OF THE BILIARY DUCTAL SYSTEM. (E.) Glenn, F. (New York Hosp.-Cornell Med. Ctr., N. Y.). Ann. Surg. 166(2):161-172, 1967.

10907 AN EVALUATION OF ANTIBIOTICS IN BILIA TRACT SURGERY. (E.) Pyrtek, L. J. (Hartford Hosp., Conn.) and S. A. Bartus. Sur Gynec. Obstet. 125(1):101-105, 1967.

10908 OUR EXPERIENCE WITH THE INDICATIONS AND LATE RESULTS OF ODDIAN PAPILLO-SPHINCTEROTOMY. (It.) Nicora, E. (Galliera Hosp., Genoa, Italy). Pathologica 58(867-868) 465-472, 1966.

10909 SURGERY FOR POSTOPERATIVE STENOSIS O THE COMMON BILE DUCT. (E.) Caluzzi F. (U. Turin, Italy), A. Mussa and G. De Giorg J. Abdom. Surg. 9(8):232-234, 1967.

10910 SURGERY OF BILIARY TRACT AND GALLBLA (Uk.) Deineka, I. Ia. Kiev, Zdorov 1966, 205pp., $1.50.

10911 ATLAS OF PER- AND POSTOPERATIVE CHOLANGIOGRAPHY. (Ger.) Kourias, B. and K. Stucke. Stuttgart, Thieme Verlag KG., 1967, 207pp., $21.75.

10912 PERCUTANEOUS, TRANSHEPATIC CHOLANGIO GRAPHY IN SURGERY OF THE BILIARY TRA (Rus.) Shor, L. M. Kaliningrad, Kaliningrad Knizhnoe izd-vo, 1966, 177pp. 90 cents.

10913 EXTRAPERITONEAL TRANSPARIETOHEPATIC CHOLANGIOGRAPHY. (Sp.) Musatadi R L. (U. Chile, Santiago), V. H. Oñate and M. Fernandez P. Rev. Esp. Enferm. Apar. Dig. 26 537-546, 1967.

10914 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY IN THE DIAGNOSIS OF JAUNDICE (E.) DeMasi, C. J. (U. S. Public Health Serv Hosp., New Orleans, La.), K. Akdamar, F. M. Hunter and R. D. Sparks. Amer. J. Med. Sci. 254(3):316-321, 1967.

10915 CHOLANGIOGRAPHIC INVESTIGATION OF CHANGES IN THE WIDTH OF THE HEPATO-CHOLEDOCHUS AFTER OPERATIONS ON THE BILIARY SYSTEM. (Cz.) Keclik, M. (Charles U., Pragu A. Huslarová, J. Zeman, J. Baudiš, M. Kovářov and F. Horáček. Cesk. Gastroent. Vyz. 21(1): 17-23, 1967.

10916 PUNCTURE OF THE GALLBLADDER DURING PERCUTANEOUS TRANSHEPATIC CHOLANGI GRAPHY. (E.) DeMasi, C. J. (Tulane U., New Orleans, La.), K. Akdamar, R. D. Sparks and F. M. Hunter. J.A.M.A. 201(4):225-228, 1967

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology had accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone	µM	micromolar
admin.	administered, administration	max.	maximum, maximal
ADP	adenosine diphosphate	mc,µc	milli-, microcurie(s)
ATP	adenosine triphosphate	mg	milligram(s)
approx.	approximately	min.	minute(s)
av.	average(d)	ml	milliliter(s)
BSP	sulfobromophthalein	mm	millimeter(s)
°C	degrees centrigrade	mo.	month(s)
cm	centimeter(s)	MTD	maximum tolerated dose)
CNS	central nervous system	ng	nanogram (10-9)
conc.	concentrate(d),	pg	picogram (10-12)
	concentration(s)	p.o.	orally
cpm	counts per minute	ppm	parts per million
DNA	deoxyribonucleic acid	r	Roentgen
e.g.	for example	RBC	red blood cells (erythrocytes)
g	gram(s)	resp.	respectively
µg	microgram(s)	Rev.	review (only in cite)
hr.	hour(s)	RNA	ribonucleic acid
i.m.	intramuscular	s.c.	subcutaneous
inj.	injected, injection(s)	sec.	second(s)
i.p.	intraperitoneal	SGOT	serum glutamic-oxalacetic transami
I.U.	international unit(s)	SGPT	serum glutamic-pyruvic transaminase
i.v.	intravenous	soln.	solution(s)
kg	kilogram(s)	U	unit(s)
LD_{50}	median lethal dose(s)	UV	ultraviolet
LDH	lactic acid dehydrogenase	vol.	volume
m	meter(s)	SBC	white blood cells (leukocytes)
M	molar		or count
mEq	milliequivalent(s)	wk.	week(s)
mM	millimolar	wt.	weight(s)
	yr.	years	

917 AFFERENT NERVOUS DISCHARGE FROM THE
CANINE LIVER. (E.) Andrews, W. H. H.
. West Indies, Jamaica) and J. F. Palmer.
art. J. Exp. Physiol. 52(3):269-276, 1967.

patic nerve strands of the dog were dissected
d analyzed for afferent impulses. Many of the
rve strands manifested resting afferent dis-
arges, which were profuse in character at times.
etylcholine (10-50 μg) inj. into either the
patic artery or portal vein resulted in
ferent discharges in all intact hepatic nerves
aluated. The highest measured potential was
μvolts and all responses seemed to be dose-
ated. In some cases, an arterial pressor
action associated with acetylcholine admin.
observed. Sensory receptor discharge was
o associated with sodium cyanide inj. into
liver circulation. A discharge (10-20 μvolts)
achieved in less than a tenth of the nerves
ted. Discharge patterns were unaffected and
activity was evoked subsequent to epinephrine
norepinephrine inj., while 2,4-dinitrophenol
not substantially affect the rate of nerve
charge. Occlusion of the inferior vena cava
also mechanical increase in the biliary
ssure did stimulate hepatic sensory activity.
is concluded from this last experiment that
contribution of the nerve fibers from the
iary receptors to the hepatic nerves is small.

18 HYPOTHALAMIC LESIONS RELATED TO INGES-
TION OF AN IMBALANCED AMINO ACID DIET.
) Nasset, E. S. (George Washington U. Sch.
., Washington, D. C.), P. T. Ridley and E. A.
enk. Amer. J. Physiol. 213(3):645-650, 1967.

e Sprague-Dawley rats were grouped into 3
ssifications: 1) normal rats; 2) rats with
ateral lesions placed in the ventromedial
lei of the hypothalamus; and 3) hyperphagic
s. The animals were fed a control diet, and
imbalanced amino acid diet, the imbalance
ng produced by adding an amino acid supplement
t contained all of the essential amino acids
ept histidine. Normal rats consumed only
-thirds as much imbalanced amino acid diet as
trol diet; rats with the hypothalamic lesions
t the ability to discriminate between the 2
ts; hyperphagic rats ingested both diets
ally and gained equally in body wt. Excessive
estion of the imbalanced diet for 6 days pro-
ed a reduction in zymogen granules in pan-
atic acinar cells and in stainable mucin in
gastric antral mucosa. These findings
onstrate that the intact ventromedial nuclei
the hypothalamus integrate the signals that
ermine the ultimate refusal of the normal
mal voluntarily to eat a diet containing an
alanced amino acid mixture.

9 UTILIZATION OF 11β-HYDROXYSTEROIDS BY
THE SALIVARY GLAND DUCTS. (E.)
Ferguson, M. M. (U. Glasgow, Scotland).
Histochemie 9(3):269-274, 1967.

The presence of pyruvate oxidase, isocitric dehydrogenase, α-ketoglutarate oxidase, succinic dehydrogenase, malate dehydrogenase and furfuryl alcohol dehydrogenase activity in the parotid, submandibular and sublingual glands (which had been removed from rats) was significant enough to indicate high metabolic activity. While the enzymes involved with the tricarboxylic acid cycle were highly active in the glands, 11β-hydroxysteroid dehydrogenase was more active in the ducts of the parotid and submandibular glands. In the ducts, 11β-hydroxysteroid dehydrogenase displayed marked substrate specificity utilizing 11β-hydroxyandrostenedione and cortisol but not 11β-hydroxyestrone or 11β-hydroxyprogesterone. The enzymes of the tricarboxylic acid cycle were also present, although less abundantly, in the ducts, indicating a highly active metabolic duct epithelium. The greater activity was in the interlobular ducts indicating different functional zones. As it has been previously shown that corticosteroids affect salivary electrolyte conc., this localization of 11β-hydroxysteroid dehydrogenase would seem to show that the ducts are the site of this corticosteroid activity.

10920 HUNGER AND SATIETY SENSATIONS IN MEN, WOMEN, BOYS, AND GIRLS. (E.) Monello, L. F. (Harvard Sch. Public Health, Boston, Mass.) and J. Mayer. Amer. J. Clin. Nutr. 20(3):253-261, 1967.

The subjective experiences of hunger and satiety were determined in 603 adolescents and adults of both sexes by means of a multiple-choice questionnaire survey; the subjects were white, middle-class Americans and included 192 men, 20-61 yr. old; 165 women, 20-67 yr. old; 101 boys, 11-15 yr. old; and 145 girls, 9-20 yr. old. It was found that, in addition to specific gastric sensations, diffuse elements of restfulness and excitability seemed salient in the hunger experience. Males appeared to experience hunger in a more specific physical way than females, whose experience appeared more diffuse and cerebral; this sex difference was more marked among adults than among adolescents. Just prior to a meal, there appeared to be an abrupt increase in mouth and throat sensations, urge to eat, and moods of cheerfulness and excitement. After several bites of food at the meal, the affective quality of physical sensations appeared to change from unpleasant to pleasant. In contrast to the many and diverse sensations of hunger, only vague sensations of gastric bulk and feelings of satisfaction and relaxation seemed to be the major sensations experienced during satiety. Adolescents described satiety as more intensely gastric than adults and seemed to continue to feel mild hunger sensations longer after the meal than adults. Diffuse feelings of warmth and relaxation appeared to be more salient elements in satiety among adults. Both male and female adults reported more intense sensations during extreme hunger than adolescents.

10921 INTESTINAL ALKALINE PHOSPHATASE IN HUMAN SERUM. (E.) Posen, S. (U. Sydney, Australia), F. C. Neale, D. J. Birkett and J. Brudenell-Woods. Amer. J. Clin. Path. 48(1):81-86, 1967.

Sera from normal blood donors were subjected to electrophoresis on strips of cellulose acetate, and classified into 2 categories, those with a slow-moving alkaline phosphatase band and those without such a band; 10 sera from each group were studied further. Phenylalanine inactivation was measured in these 20 sera; alkaline phosphatase activities were determined in the presence and absence of 5×10^{-3} M L-phenylalanine. Antihuman intestinal alkaline phosphatase activity was assessed. With 5×10^{-3} M L-phenylalanine, sera without a slow-moving zone were inactivated to a mean of 59.3% of their original activities, whereas those with a slow-moving zone retained only 49.8% of their activities. When the phenylalanine conc. in the assay system was 2.5×10^{-3} M, the mean activity of sera not containing a slow-moving zone was 84.9±7.4% of the controls, whereas the mean activity of the sera with the slow phosphatase zone was reduced to 73.9±5.5% of the control sera. The effect of the anti-intestinal alkaline phosphatase preparation was such that those without the slow-moving band lost a mean of 3.5% of their original alkaline phosphatase activity, and those with a slow-moving band lost a mean of 12%; this difference was significant. These findings show that normal sera containing electrophoretically slow-moving alkaline phosphatase are more susceptible to L-phenylalanine and to anti-human intestinal alkaline phosphatase antibody than normal sera that do not contain this slow-moving component. A good correlation existed in individual sera between phenylalanine sensitivity and antibody sensitivity. These results constitute further evidence that slow-moving alkaline phosphatase is of intestinal origin. In sera containing intestinal alkaline phosphatase, this enzyme accounts for approx. 20% of the total alkaline phosphatase activity.

10922 THE ROLE OF GLYCOPROTEINS AND OF NEURAMINIC ACID IN THE GASTRIC AND INTESTINAL MUCOUS MEMBRANES. II. (Rus.) Mnatsakanian, A. A. Zh. Eksp. Klin. Med. 7(1):25-31, 1967.

Albino rats (120 divided into 7 groups) were kept on the following diets before sacrifice: Group 1, starvation for 24 hr. (control); Group 2, starvation for 24 hr. followed by feeding with milk; Group 3, the same, but feeding with meat; Group 4, the same, but feeding with bread; Group 5, the same, but feeding with bread, milk, and tomatoes; Group 6, feeding continuously with bread and meat; Group 7, starvation for 48 hr. Regardless of the functional state of the digestive tract the glycoprotein content of the muco membranes decreased in the following order: stomach (700-1300 mg%), duodenum (480-870 mg%), and the distal part of the small intestine (480-810 mg%). The lowest glycoprotein content of t mucous membranes was found in animals starved f 24 hr. (Group 1: stomach, 700 mg%; duodenum, 480 mg%; distal part of the small intestine, 480 mg%). After feeding (Groups 2-6) or prolon starvation (Group 7) the glycoprotein content o the mucous membranes increased by 330-600 mg%. This increase depended on the diet and the inte val between feeding and sacrifice. Feeding wit bread or meat led to a more pronounced increase than with milk, max. levels of glycoproteins being reached 1-2 hr. after feeding. The neuraminic acid content of the mucous membranes of animals starving for 26 hr. (stomach, 63 mg%; duodenum, 43.5 mg%; small intestine, 42.5 mg%) also increased by 33-74.5 mg% after prolonged starvation or feeding with any of the foods exc milk. Max. levels of neuraminic acid were obse 1-2 hr. after feeding. Animals fed with bread meat (Group 6) had the highest levels of neuraminic acid in the mucous membranes (gastric, 137.5 mg%; duodenal, 81.5 mg%; intestinal, 75 m It is considered that increased levels of glyco teins and of neuraminic acid may protect the mucous membranes against the action of proteoly enzymes.

10935 ORGAN CULTURE OF FETAL RAT PANCREAS: 1. EFFECTS OF GLUCOSE, OTHER COMPOUNDS OF THE CULTURE MEDIUM AND A SULFAMIDE ANTI-DIABETIC AGENT. (Fr.) Vecchio, D. (U. Geneva, Switzerland) and A. E. Gonet. *Helv. Physiol. Pharmacol. Acta* 25(1):103-122, 1967.

Excised pancreas from 18-day-old fetal rats were cultured for up to 1 wk. Insulin was measured in the homogenates of pancreatic tissue by a radioimmune method. Glucose was increased in the cultures of some explants and in others tolbutamide was present in the culture medium (81 µg/ml). The exocrine tissue retained a fetal appearance although organized into acini to some degree. Considerable differentiation and multiplication of endocrine cells occurred with the rise of typical β-granules during the culture period. The pancreatic insulin content measured biologically or immunologically was less than 0.5 mU/mg at the time of explantation and increased during the culture period to 3.5 mU/mg at 4 days and 14.0 mU/mg at 7 days thus demonstrating the occurrence of insulin biosynthesis *in vitro*. The conditions most favorable for this development include the addition of 5% each of serum and fetal extract to the culture medium. Both glucose and tolbutamide exerted trophic effects upon pancreatic explants in the culture. The optimal conc. of glucose was between 11 and 16.5 mM resulting in a relative increase of endocrine tissue without exhaustion or degeneration of the β-cells; this was indicated by the increase of insulin content in the explants. Tolbutamide caused an increased differentiation of endocrine tissue but without increased insulin content of the tissue. It is possible that with tolbutamide the insulin was released into the medium.

10936 A COMPARATIVE STUDY OF THE ULTRASTRUCTURE OF MICROVILLI IN THE EPITHELIUM OF SMALL AND LARGE INTESTINE OF MICE. (E.) Mukherjee, T. M. (U. Otago Med. Sch., Dunedin, New Zealand) and A. W. Williams. *J. Cell Biol.* 34(2):447-461, 1967.

The fine structure of the microvilli on jejunal and colonic epithelial cells of the mouse intestine was analyzed and compared. In these 2 locations, the microvilli demonstrated a remarkably similar fine structure with respect to the thickness of the plasma membrane, the extent of the filament-free zone, and the characteristics of the microfilaments situated within the microvillous core. Some of the core microfilaments appeared to continue across the plasma membrane limiting the tip of the microvillus. The chief difference between the microvilli of small intestine and colon was in the extent and organization of the surface coat. In the small intestine, in addition to the commonly observed thin surface fuzz reported by earlier workers, occasional areas of the jejunal villus showed a more conspicuous surface coat covering the tips of the microvilli. The surface coat was an integral part of the epithelial cells. In contrast to the jejunal epithelium, the colonic epithelium was endowed with a thicker surface coat. Variations in the organization of the s face coat at different levels of the colonic crypts were also observed.

10937 LONGITUDINAL DIFFERENTIATION OF THE SMALL INTESTINE. (E.) Baintner, K. Jr. (U. Med. Sch., Budapest) and B. Veress. *Nature (London)* 215(5102):774-776, 1967.

Morphological differences were noted between t upper and lower parts of the small intestine c suckling rats during a histological study of γ globulin absorption. Duodenal epithelial cell of these rats resembled those of adults, but their ileal cells were of a different type, exhibiting large vacuoles giving the impressic of being "hollow" in paraffin-embedded sectior The vacuoles were also clearly visible in the unstained suspension of living cells and conta fluid but no fat or mucus. On staining with mucicarmine, only a few goblet cells were note among the "hollow" cells; the vacuoles of the latter frequently contained periodic acid-Schi positive inclusion bodies, yellow in color in unstained and eosinophilic in stained preparations. Transition between the "hollow" and nc mal epithelial cell was gradual. Macroscopica the upper part of the small intestine of the suckling rat appeared milky white, whereas its lower part, containing the hollow cells, was yellowish-brown in color; the inclusion bodies were probably responsible for this coloration. The ileal cell type just described was also found in the mouse and guinea-pig, but not in the dog, goat, pig and cat; unlike the rat, guinea-pigs had no inclusion bodies in their "hollow" cells.

10938 CURRENT VIEWS ON THE MICROSCOPIC STRUCTURE OF THE LIVER. (E.) Kuś, (Dept. Descriptive & Topograph. Anat., Cracow, Poland). *Acta Med. Pol.* 8(2):185-194, 1967.

Current studies by the microcorrosion method support the concept that the portal lobule supplied by the proper interlobular triad is the structural and functional U of the liver which constructed of liver platelets, not trabeculae The portal lobule has a triangular shape and i the center of the triangle, surrounded by a variable amount of connective tissue, lies the portal triad with the central veins on its per ery. In corrosion preparations, these areas h the appearance of pyramids composed of casts o the capillary sinusoids. The capillary sinuso of the liver stretch from the terminal venules the central veins. They are lined with endoth which is discontinuous and they differ from ordinary capillaries with respect to the prese

Kupffer cells with pronounced phagocytic
operties and the capability of storage and pro-
ction of antibodies. The distribution of these
lls is determined by the scheme of the portal
bule; the greatest conc. in the area of the
rtal triad. The liver cells are arranged into
atelets 1 cell in width. Between 2 adjacent
patocytes a bile ductule runs, the walls of
ich are formed by grooves covered with micro-
lli. The hepatocytes are in contact with the
pillary sinusoids through microvilli projecting
to the spaces of Disse.

939 VASCULAR ARCHITECTURE OF THE GASTRIC
WALL IN MAN AND SOME EXPERIMENTAL
IMALS. (Pol.) Karmański, J. (Inst. Norm.
at., Zabrze, Poland) and A. Pisarski. Folia
rph. (Warsz.) 25(4):615-621, 1966.

ood vessels of the gastric wall of man, dogs,
bbits and rats, inj. with pigmented latex and
ained by the method of Grant and Slonimski were
udied and compared. The subserosal vascular
twork is closely connected with the plexus of
muscular membrane. The muscular membranes
supplied by branches from the main gastric
ssels and from the submucosal plexus. In man
dog venous and arterial networks are located
ween the circular and longitudinal muscular
ers of the stomach. In the submucosal layer,
addition to the submucosal plexus, another
ller one, composed of veins typical for con-
tive tissue, was found. In man and dog, besides
venous network of the submucosa, there exists
ve the muscularis propria of the mucosa another
ous plexus. In dogs, blood vessels in the
osa which, until recently, were described as
iating arteries are actually veins. They have
racteristic constrictions and lead to the
xus above the muscularis propria of the mucosa.
vascularization of the mucosa was almost iden-
al in all the species. The greatest similar-
es were found between the gastric vasculariza-
n of dog and man and greatest differences
ween that of the rat and man.

10952 AN IMPROVED TURBIDIMETRIC ANALYSIS OF POLYETHYLENE GLYCOL UTILIZING AN EMULSIFIER. (E.) Malawer, S. J. (Walter Reed Army Med. Ctr., Washington, D. C.) and D. W. Powell. Gastroenterology 53(2):250-256, 1967.

Polyethylene glycol is a commonly used indicator substance for studying intestinal absorption. The addition of a water-soluble vegetable gum (gum arabic or gum ghatti) to the reaction mixture of the turbidimetric analysis of polyethylene glycol produced the following: a stable, prolonged peak of max. turbidity which makes precise timing during the determination unnecessary; a linear polyethylene glycol conc. optical-density relationship over a useful range of polyethylene glycol conc; and an accurate and reproducible method of analysis. When gum arabic was present, max. turbidity occurred within 60 min. with a polyethylene glycol range of 200-1000 mg/100/ml. Linearity for this conc. range was obtained with a conc. of gum arabic of 10.0-14.0 mg/liter. The optimum conc. of linearity over the same polyethylene glycol range for gum ghatti was 2.0 mg/liter. The test of reproducibility and recovery was conducted on jejunal perfusions from 4 normal subjects where the coefficient of variation ranged from 0.53%-1.5% and the recovery ranged from 100.0%-101.3%. Centrifugation is indicated when debris conc. is greater than 1%. In vivo perfusion studies of jejunum, ileum, cecum and colon of guinea pigs and rats using this analysis showed no difference in reproducibility between the 2 animals, the different intestinal segments or the 2 emulsifiers used.

10953 STRUCTURAL AND FUNCTIONAL ORGANIZATION OF THE BRUSH BORDER OF INTESTINAL EPITHELIAL CELLS. III. ENZYMIC ACTIVITIES AND CHEMICAL COMPOSITION OF VARIOUS FRACTIONS OF TRIS-DISRUPTED BRUSH BORDERS. (E.) Eichholz, A. (Rutgers Med. Sch., New Brunswick, N. J.). Biochim. Biophys. Acta 135(3):475-482, 1967.

The composition of the subunits of the intestinal brush border of the hamster jejunum was studied. Fractions obtained after Tris disruption and subsequent density-gradient centrifugation were analyzed for their enzyme and chemical content; the fractions included a major membrane component, a minor membrane component, microvillus cores and 2 that were unidentified. The major membrane component fraction contained all of the maltase, invertase, alkaline phosphatase, lactase, isomaltase, trehalase and leucyl naphthylamide hydrolase activities of the brush border, and also contained ATPase. A different ATPase activity was found in 1 of the morphologically identified fractions; this appeared to be associated with a fibrillar material which can be formed from this fraction by appropriate treatment. Lactase activity was occasionally found to be differently distributed from the other disaccharidases, i.e., an appreciable amount appeared in the minor membrane component. No enzymatic activities were found in the fraction composed of microvillus cores. All fractions were analyzed for phospholipid, cholesterol, carbohydrate, protein and DNA; a cholesterol: phospholipid ratio of 1:1 was found in the major membrane fraction.

10954 INTERACTIONS IN THE INTESTINAL HYDROLY AND ABSORPTION OF A FOODMIXTURE. A CONCEPT OF PROXIMAL-DISTAL ABSORPTION GRADIENT. (E.) Ugolev, A. M. (Pavlov Inst. Physiol., Leningrad, USSR), N. N. Jesuitova, N. M. Timofeeva, M. B. Chernjahovskaja and P. De Laey. T. Gastroent. 10(2):152-159, 1967.

The hydrolysis of different test substances (disaccharide, dipeptides and tributyrin) either alone or in combination was studied and compare during incubation with everted intestinal segments taken from white Wistar rats. The initial conc. of the different test substances in Ringer soln. were as follows: 0.2% of a tributyrin emulsion containing 0.01% of sodium deoxycholat 0.3% soln. of dipeptide (glycyl-L-leucine) and 0.25, 0.5 or 1.0% sucrose soln. All incubations were performed at room temperature (22-24°) in metabolic shaker (110 strokes/min.). The hydrolysis rate of the dipeptide was very rapid in the initial reaction stages and showed a typical curved-time correlation. In the presen of 1% sucrose soln. a small and variable intensification of dipeptidase activity was noted. In the presence of tributyrin a significant inhibition of hydrolysis of dipeptide was noted during the entire period of incubation. In the presence of the total test mixture, the inhibit was even more pronounced. Neither the presence of tributyrin nor addition of dipeptide to a 1% soln. of sucrose containing tributyrin had any influence on disaccharidase activity. Hydrolys of tributyrin was slightly activated when the incubation soln. contained 0.3% of dipeptide. There was an inhibition of sucrose hydrolysis a low sucrose conc. (0.25% soln.) in the presence of tributyrin, but this inhibition disappeared when higher conc. of sucrose (0.5 and 1.0%) wer employed. It is suggested that the proximal-distal digestion gradient in the intestine seem to depend much more on the molecular characteristics and conc. of the substrates than on the enzymatic and other activities of the small intestine. Lipids inhibit dipeptide hydrolysis which in turn enhance lipolytic activity. The sequences of hydrolysis and absorption of carbohydrates and peptides is dependent upon their relative conc.

10955 POSTNATAL CHANGES OF ACTIVITY AND ELECTROPHORETIC PATTERN OF JEJUNAL AN ILEAL NONSPECIFIC ESTERASE AND ALKALINE PHOSPHATASE OF THE RAT. EFFECT OF ADRENALECTOMY. (E.) Pelichová, H. (Charles U., Prague),

Koldovský, A. Heringová, V. Jirsová and J.
ml. Canad. J. Biochem. 45(9):1375-1384, 1967.

white Wistar rats the activity of nonspecific
erase (substrate, β-naphthyl acetate) in the
unum and ileum increased during the postnatal
iod of development. Electrophoresis showed
t distribution of this enzyme was different
these 2 parts of the intestine in suckling
s, whereas the zymogram was the same for both
ts in the adult animal. In intact rats, the
ree of inhibition of nonspecific esterase
ivity by 10^{-4} M physostigmine, 5×10^{-6} M
thyl p-nitrophenylphosphate, and 0.4 M NaCl
different, but there were no differences with
1 inhibitor between the jejunum and the ileum
suckling and weanling rats. Adrenalectomy at
ays of age did not influence the activity of
enzyme, but at 14 days of age it inhibited
rise of activity in the jejunum and ileum.
enalectomy influenced the sensitivity of non-
cific esterase activity to inhibition by
sostigmine and diethyl p-nitrophenyl phos-
te. When cortisone was admin. to adrenal-
omized rats, certain characteristics of the
yme (specific activity, sensitivity to various
bitors, zymogram) were, in most cases, com-
ble with those of preparations from normal
rols. The activity of alkaline phosphatase
strate, β-naphthyl phosphate) in the jejunum
ed practically no change during postnatal
lopment, but in the ileum it decreased.
ge in the zymogram was of the same type in
ileum and jejunum. Adrenalectomy at 7 days
ge was followed by a fall in activity in the
m that was apparent at 14 days of age, but
zymogram was not affected. Adrenalectomy on
14 did not produce an apparent change by day
but there was retention of the earlier
trophoretic pattern. When cortisone was
n. to adrenalectomized rats, certain char-
ristics of the enzyme (specific activity,
gram) were comparable with those of prepara-
s from normal controls.

ELECTRICAL POTENTIAL ACROSS THE RAT
SMALL INTESTINE STIMULATED BY ADENOSINE
HOSPHATE. (E.) Kohn, P. G. (U. Sheffield,
and), H. Newey and D. H. Smyth. Nature
don) 215(5108):1395, 1967.

2 adjacent 6-cm sacs from the everted mid-
num, bathed in 30 ml of bicarbonate saline,
electrical potential was recorded across the
of the rat intestine in response to ATP.
tion of 1 mM ATP to the mucosal fluid caused
se in potential after 15 sec., which reached
ak in 60-70 sec. and fell to the original
after approx. 6 min.; the mean potential
ease was 2.85 (±0.20 millivolt), the serosal
being positive. The change was considerably
r than that obtained from addition of trans-
ble hexoses or amino acids. A conc. of 0.1
P caused a potential of 1.6 millivolts, and
0.01 mM ATP produced a potential of 0.6
volts. Addition of adenosine monophosphate or adenosine diphosphate (1 mM) produced a much smaller effect, thereby suggesting that ATP is specific and probably supplies energy for an ionic transport process. The effect of several inhibitors was studied. Phlorhizin (2×10^{-4} M) had no effect on the ability of ATP to stimulate the potential; addition of 2,4-dinitrophenol (2×10^{-4} M) prevented the development of a potential by ATP; ouabain (10^{-3} M) in the serosal fluid caused approx. 50% inhibition of the potential generated by ATP, but had no effect when present in the mucosal fluid. The effect of ionic environment was studied by replacing the NaCl in the bathing fluids by mannitol, choline chloride or KCl; replacement with KCl prevented the potential that is stimulated by ATP, but replacement with mannitol or choline chloride increased the ATP potential to approx. 6 millivolts. In the presence of galactose, ATP caused an increase in potential identical to that in the absence of galactose, e.g., 2 mM galactose gave a potential of 2 millivolts, whereas 2 mM galactose together with 1 mM ATP gave 5 millivolts; in the presence of glucose (2 mM), a smaller increase (1.5 millivolts) was observed when ATP was added. These findings show that ATP in low conc. stimulates the potential across the rat small intestine and are in accord with the action of ATP on a Na pump; these experiments appear to provide the first demonstration that utilization of ATP plays a direct part in the intestinal transfer process.

10957 FATTY ACID ABSORPTION AND METABOLISM IN PROTEIN-CALORIE MALNUTRITION. I. EFFECT OF FAT-FREE AND FAT-CONTAINING DIETS ON FECAL FATTY ACIDS. (E.) Underwood, B. A. (Columbia U., New York, N. Y.), S. A. Hashim and W. H. Sebrell, Jr. Amer. J. Clin. Nutr. 20(3): 226-232, 1967.

Fatty acid absorption was studied in 6 children (3 of each sex; 8-36 mo. old) with protein-calorie malnutrition upon their admission to hospital and at intervals during treatment with a high-protein formula of casein-supplemented skimmed milk containing less than 1 g of fat/day with and without added oil from the day of hospitalization and in 2 children given formula with added oil. The fatty acid composition of the oil was 0.7% myristic acid, 17.8% palmitic acid, 2.6% stearic acid, 37.0% oleic acid, 41.0% linoleic acid and 0.9% unidentified fatty acids. Balance studies were repeated after 9-11 days and after 17-22 days of treatment. Quantitative and gas-liquid chromatographic data obtained from fatty acid analysis of fecal lipids indicated that a significant amount of endogenous fat was excreted, and that this amount was affected very little by feeding diets containing a vegetable oil. Oils in amounts of 33 g/day given at the time of hospitalization did not cause diarrhea or vomiting. Both quantitative and chromatographic data revealed good absorption of p.o.

admin. diets rich in unsaturated fatty acids. In contrast, after nearly 3 wk. of treatment, the level of excreted fatty acids was increased when butterfat was the primary source of dietary fat.

10958 STEATORRHEA IN RATS WITH INTESTINAL DIVERTICULA: EFFECTS OF CHANGING DIETARY DISACCHARIDE AND OF COPROPHAGY. (E.) Hamilton, J. R. (U. Toronto, Canada). *J. Nutr.* 91(4):461-467, 1967.

The creation of a self-filling intestinal diverticulum in rats caused an impairment of fat absorption 4 wk. following surgery, whereas this did not occur in rats which underwent the creation of a self-emptying diverticulum or a sham operation. Initially, the animals were on a diet rich in lactose and then the dietary disaccharide was changed to sucrose which did not alter fat excretion in any group. With sucrose, the total food intake increased. The mean body wt. increased in all groups following the surgery, but mean weight of the group with the self-filling intestinal diverticulum (Group 1) was significantly lower than those in the sham group. The mean value for tail length in this group also was significantly less than either of the other 2 groups. Mean hemoglobin levels were not significantly altered in any group. The postoperative mortality rate in the first group was high with 7 deaths in 16 rats but after this first wk. no deaths occurred in any group. At necropsy, gross abnormalities were confined to the first group: the pouches were enlarged to 2-3 times their original length and diameter and were filled with foul, turbid fluid. In 5 of 9 rats, altered blood was found in the pouches. Microscopically, these pouches had villi that were regular but elongated.

10959 A PLASTIC-CANNULATED INTESTINAL LOOP TO STUDY EFFECTS OF ANESTHESIA ON Ca ABSORPTION. (E.) Cramer, C. F. (U. British Columbia, Vancouver, Canada), S. J. Sadler and R. G. Schulz. *J. Appl. Physiol.* 22(6):1149-1150, 1967.

In order to obviate intestinal intussusception and skin overgrowth, dogs were prepared with intestinal loops perfused with $CaCl_2$ (30 mg Ca/100 ml) made up to 300 milliosmols/liter and which were distinguished by having special nylon cannulae inserted at both ends, which were then brought to the skin surface. This same procedure was repeated and supplemented by admin. of sodium pentobarbitone (30 mg/kg) on the same dogs 4-7 days later. Supplementary barbiturate inj. (6 mg/kg) were also given as required. Of the total of 62 half-hr. measurements made on the conscious dogs, a mean Ca absorption value of 36.4 ± 1.6%/0.5 hr. was observed as compared to a mean value of 43.0 ± 2.5% for anesthetized dogs. Absorption of Ca (mg/0.5 hr.) was 12.8 ± 0.53 and 14.2 ± 0.82 mg/0.5 hr. for conscious and anesthetized dogs, resp. Conscious dogs manifested only a 3.2% standard error as compared to one of 5.8% for anesthetized dogs. These results indicate that barbiturate anesthetization did not depress Ca absorption.

10960 ZINC INTERFERENCE WITH COPPER ABSORPTION IN RATS. (E.) Van Campen, D. R
(US Dept. Agric., Ithaca, N. Y.) and P. U. Scaife. *J. Nutr.* 91(4):473-476, 1967.

An interference in Cu absorption was detected i
Sprague-Dawley rats who were admin. simultaneou
(^{64}Cu tracer, 1.0 μg) and Zn (1.0 mg) in ligate
in vivo segments of the duodenum (approx. 7 cm
in length), whereas in those rats which receive
the tracer Cu by this same route, but the Zn by
i.p. admin. 2 or 18 hr. prior to the admin. of
the ^{64}Cu, the copper absorption was similar to
that of the control animals. Measurements were
made 3 hr. after the admin. of the Cu. Intraduodenal admin. of Zn also tended to decrease t
relative proportion of ^{64}Cu in the liver and to
increase the proportion in the kidneys. There
was also, a significant increase in the serum Z
levels. However, in this case, neither the Zn
nor the Cu levels in the liver, RBC, heart and
kidneys were significantly altered. When the
i.p. admin. of Zn was made at the same time as
the admin. of Cu, the serum level of Zn was
greater than in the controls, but when it was
admin. 2 or 18 hr. prior to the Cu, the serum Z
level was like the controls. These data indica
that Zn does not depress Cu uptake by accumulat
ing in some nonintestinal tissue and, subsequen
interfering with Cu absorption, but, rather, th
impairment is mediated primarily by the direct
effects of Zn either in or on the intestine.

10961 THE EFFECT OF GALACTOSE ON PHENYLALA
TRANSPORT AND ITS DAMAGE TO THE MUCOS
CELLS OF THE RAT INTESTINE. (E.) Casey, M. G.
(U. Med. Clin. Lausanne, Switzerland) and J. P.
Felber. *Gastroenterologia (Basel)* 107(4): 209-215, 1967.

Segments of male Wistar rats intestines incubat
for 1 hr. at 37°C in Krebs bicarbonate-buffer
containing 5 mM of phenylalanine-U-C^{14} in the
presence of 30 mM of galactose showed a signifi
cant reduction of phenylalanine uptake. This
decrease was not seen with 5 mM of galactose.
In addition, preincubation of tissues for 45 mi
in 30 mM galactose followed by incubation with
labeled phenylalanine (with 200 mg glucose/100
caused a reduction in the uptake of phenylalanine as compared to preincubation Krebs
bicarbonate-buffer alone. No reduction occurre
with preincubation in 5 mM galactose. In further experiments it was seen that the presence of galactose increased the rate of phenylalanine release from the tissues. Conversely, the addition of 10 mM phenylalanine
to the incubation medium containing 5 mM galactose showed a decrease in the galactose uptake by the tissues. Additional galactose as well as phenylalanine stimulated the release of labeled galactose from the tissue. Examination of the tissue showed that galactose caused some damage to mucosal cells; nevertheless, these data indicate that a common transport mechanism exists in the intestine for galactose and phenylalanine.

2 ACTION OF L-ALANINE ON THE FLUXES OF
INORGANIC IONS ACROSS THE INTESTINAL
HELIUM OF THE GREEK TORTOISE. (E.)
es-Baillien, M. (U. Liege, Belgium) and E.
ffeniels. Life Sci. 6(12):1257-1262, 1967.

g symmetrical portions of epithelium isolated
the jejunum of the Greek tortoise and mea-
g unidirectional fluxes of Cl with ^{36}Cl, it
hown that a spontaneous potential difference
s between the mucosal and the serosal fluids
his can be abolished by means of an external
romotive force. With Cl, the net flux was
s directed towards the luminal side of the
elium. When L-alanine was added to the
m in the mucosal soln. a decrease, followed
reversal of the flux, always occurred
er the spontaneous potential was or was not
ed by an external source of current. These
suggest a direct relationship between an
e transport of L-alanine and the active
port of Cl ions. Such reproducible results
not obtained when L-alanine was added to
ystem in the presence of either Na- or K-
s. In both cases the results were too
ble to be conclusive, but it would seem that
nine has no effect on K-fluxes.

MILK PROTEIN PERMEABILITY OF THE
INFANTILE INTESTINE FROM THE ASPECT OF
ODY REACTION. (E.) Kodama, T. (Wakayama
Coll., Japan) and K. Hiroi. Acta Paediat.
[Overseas] 8(16):29-39, 1966.

ody to cow's milk in the blood of infants
etermined using the tannic acid-treated
gglutination method; the highest level was
in infants given a completely artificial
ng. Antibody positives were higher in the
in which cow's milk or cow's milk prepara-
was begun before the fifteenth day after
, compared to those given artificial feed-
fter the fifteenth day. The high positive
ody rate present in the group in which
icial feeding was begun before 15 days of
as attributed to 2 factors, namely, the
tibility of cow's milk protein and the
ability of the intestinal wall at this
of life. Determination of the antibody
ding to each protein fraction revealed the
st rate for α-casein, while the antibody
st α-lactalbumin and β-lactoglobulin was
When α-casein was admin. p.o. in the rat,
ody was found only in the animals given
ein in the newborn stage; it was not
ved when given at later stages.

DIFFERENCES IN THE MECHANISM OF
INTESTINAL ABSORPTION OF CARDIOTONIC
IDS AND OTHER DRUGS. (Ger.) Lauterbach, F.
us Biol. Inst., Cologne, Germany), C.
, D. Nitz and K. Prescher. Naunyn
edeberg Arch. Pharm. Exp. Path. 257(4):
57, 1967.

Isolated rat intestinal loops about 30 cm long (beginning 5 cm beyond the pylorus) were perfused with 40 ml of a modified Krebs-Ringer soln. at 37.5°C; perfusion duration was 45 or 90 min. The cardiotonic steroids and other compounds tested were added to the perfusion fluid; when compounds with low solubilities in H_2O were studied, the perfusion fluid contained 4% ethanol by vol. During a trial the intestinal loop was placed either in a moist chamber or in a 60-ml bath containing the same Krebs-Ringer soln. as the perfusion fluid (without the compound under test). The entire system was oxygenated. Altogether the absorption of 6 cardiotonic steroids and 3 other drugs in several conc. was measured; the amounts of absorbed drug were determined from the fluid absorbed or in the soln. bathing the loop checked against the amount in the wall of the loop and that in the perfusate. The absorption rates were calculated from these values. With increasing drug conc. in the perfusate: 1) The absorption rates of hydrocortisone and lysergic acid diethylamide remained constant and the absorption rate of quinine increased only slightly; 2) the absorption rate of digitoxin increased and although the amount was small (statistically not significant), the increment was present under all experimental conditions; 3) the absorption rates of strophanthidin, ouabain, deslanoside, convallatoxol, and convallatoxin decreased. The decreased absorption rate of convallatoxin was more marked with greater conc. of the compound in the perfusate; when the glycoside was increased 40-fold, the absorption rate fell to 5% of its original value. Bathing the loop instead of using the moist chamber doubled the absorption rates of bath hydrocortisone and convallatoxin. The absorption of hydrocortisone was not influenced by convallatoxin but the absorption of convallatoxin was inhibited by hydrocortisone. Polar cardiotonic steroids seem to be mainly absorbed by a transport system which presents the kinetics of saturation. An absorption by diffusion probably occurs only when the condition of the intestinal wall and the experiment are not optimal.

10965 INFLUENCE OF Na+ ON THE INTESTINAL ABSORPTION OF THE CARDIAC GLYCOSIDE CONVALLATOXIN. (Ger.) Lauterbach, F. (Madaus Biol. Inst., Cologne, Germany), C. Gerber, D. Nitz and K. Prescher. Naunyn Schmiedeberg Arch. Pharm. Exp. Path. 257(4):458-473, 1967.

Isolated rat intestinal loops were used to study the interaction of Na, H_2O, and convallatoxin and also glucose and hydrocortisone during absorption as the loops were perfused with soln. of different Na conc. The av. values for the Na and H_2O absorbed increased continuously when the Na levels of the perfusate were elevated. The av. amount of hydrocortisone absorbed was raised by elevating the Na of the perfusate; the increased amount of hydrocortisone absorbed was proportional to the increased amount of H_2O simultaneously absorbed; its conc. in the absorbed fluid and the ratio of hydrocortisone absorbed to Na absorbed remained constant. Unlike hydrocortisone the av. amount of absorbed glucose and of convallatoxin lagged behind the increasing absorption of H_2O and Na. Therefore at high Na conc. in the perfusate, the conc. of both glucose and convallatoxin in the absorbed fluid and the ratios of the absorbed amounts of glucose to absorbed Na and of convallatoxin to Na, resp., were smaller than the corresponding values obtained in experiments with low Na conc. in the perfusate. The Na-dependent absorption of convallatoxin was the same as that previously described for the Na-dependent absorption of glucose. The regression coefficient decreased with increasing Na conc. of the perfusion soln. The relative absorption rate of convallatoxin decreased with higher conc. of the glycoside in the perfusate; this effect occurred at a Na conc. as low as 10 mM. The similar dependence of the absorption of glucose and convallatoxin indicates that cardiosteroids can be absorbed by a transport mechanism.

10966 ACTION OF CARDIAC GLYCOSIDES UPON THE ISOLATED SMALL INTESTINE. (Ger.) Forth, W. (U. Saarland, Homburg/Saar, Germany) and W. Rummel. *Helv. Physiol. Pharmacol. Acta* 25(1):8-23, 1967.

Guinea pig jejunal segments (8 cm long) were perfused for 2 hr. with oxygenated Tyrode soln. containing the drug to be tested; the preparations were maintained in a moist chamber at 37°C. The fluid absorbed through the wall of the loop was collected from the bottom of the chamber. In another series everted-sac preparations (5-cm long) were made from jejunal segments, tied at both ends, inj. with Tyrode soln. (serosal side) and placed in 10 ml of Tyrode soln. under 1.5 atmospheres pressure of 95% O_2 and 5% CO_2, at 37°C for 2 hr.; after this the glucose conc. was determined in the serosal fluid. The effects of digitoxin, ouabain and proscillaridin (glycoside from bulbus *Scillae*) on Ca, Na, and Cl ions, H_2O and glucose absorption were studied; all 3 glycosides inhibited the absorption of Ca, glucose, Na and H_2O. The degree of inhibition by the particular glycoside varied in different jejunal regions; using equimolar conc. of glycosides, in the distal jejunal segment the inhibition was double that in the proximal segment. The transport processes were not influenced to the same extent; in the proximal segment a reduction of about 50% in glucose absorption occurred with digitoxin of 1×10^{-5} M, of 5×10^{-5} M and with proscillaridin of 5×10^{-6} M. Na and H_2O were not affected at these conc., but at these conc. digitoxin and proscillaridin reduced Ca as well as glucose absorption. Using the everted-sac preparation, the transport of glucose was inhibited by proscillaridin and ouabain whether the glycoside was added on the mucosal or on the serosal side; the threshold conc. for ouabain on the serosal side (5×10^{-6} M) being smaller than the equally effective dose on the mucosal side. The situation was reversed with proscillaridin where the mucosal side was more sensitive; digitoxin was also more effective on the mucosal side. It is suggested that the different behavior of the cardiac glycoside is caused by differences in polarity and in their affinity for proteins.

10967 EFFECT OF COMPLEX FORMATION ON DRUG ABSORPTION. IV. ROLE OF INTRAGASTRI DIFFUSION IN THE ABSORPTION OF FREE AND CAFFEIN COMPLEXED SALICYLIC ACID FROM THE RAT STOMACH. (E.) Reuning, R. H. (State U. of New York, Buffalo) and G. Levy. *J. Pharm. Sci.* 56(7): 843-847, 1967.

Gastric absorption of salicylic acid complexed with caffeine was evaluated in rats under conditions in which the complex soln. was eithe stirred or left unstirred in the stomach. Stirring was effected by either employing a static stirrer in which the implanted microstirrer was not rotated during the absorption period or a rotating stirrer in which stirring was started 5-7 min. after salicylic acid inj. and maintained during the rest of the 1-hr. absorption period. The stomach along with the residual drug soln. was removed after the absorption period. The stomach and its content were homogenized and analyzed for unabsorbed salicylic acid. The overall absorption rate of salicylic acid was reduced uniformly under both conditions of stirring and also for nonstirring tests. In addition, stirring had no appreciabl effect on the absorption rate of free salicylic acid, salicylic acid complex or for ethanol. These findings indicate that under these experimental conditions, the diffusion of neith free salicylic acid nor salicylic acid complex in the absorption of salicylic acid is rate-limited. It is probable that the observed decreased absorption of salicylic acid is the result of a reduced thermodynamic activity of salicylic acid brought about by its complexing with the caffeine.

10968 VITAMIN B_{12} ABSORPTION STUDIES---THE EFFECT OF CARBACHOL AND GASTRIN ON TH ^{57}CO-LABELLED VITAMIN B_{12} PLASMA LEVEL ABSORPTI TEST IN PATIENTS WITH PERNICIOUS ANAEMIA. (E.) Armstrong, B. K. (Roy. Perth Hosp., Australia) and H. J. Woodliff. *Med. J. Aust.* 1(16):819-82 1967.

Vitamin B_{12} absorption in each of 12 patients with pernicious anemia was studied on 3 occasio by the use of unstimulated, carbachol-stimulate (a dose of 0.25 mg of carbechol admin. i.m. 30 min. before the test) and gastrin-stimulated (135 U [µg] of gastrin admin. i.m. 30 min. before the test) ^{57}Co-labeled vitamin B_{12} plasma level tests. After an overnight fast, the vitamin B_{12} absorption test was begun with a p.o. dose of 0.8 µg of ^{57}Co-labeled cyanocobalamin; 6 hr. later 1000 µg of unlabeled hydroxocobalamin was admin. i.m., and 2 hr.

this blood was drawn for counting of the
activity in the plasma. Levels of less than
of the dose/liter were considered indica-
of malabsorption of vitamin B_{12}, those
er than 0.65% were indicative of normal
ption and those from 0.45%-0.65% were
dered equivocal. Only 2 anomalous (equivocal)
ts occurred. The results indicated that
er carbachol nor gastrin had a significant
t on vitamin B_{12} absorption as assessed by
test.

FURTHER STUDIES ON THE MECHANISM OF
ABSORPTION OF VITAMIN A AND CHOLESTEROL.
David, J. S. K. (Indian Inst. Sci.,
lore) and J. Ganguly. Indian J. Biochem.
14-17, 1967.

a 24-hr. starvation period, normal male al-
rats were given p.o. 7.7 μmoles of 4-^{14}C-
sterol ester containing 50,000 counts/min.,
.5 μmoles of retinyl acetate, each compound
dissolved in 0.5 ml of peanut oil. Almost
f the cholesterol ester hydrolase of the
tinal mucosa of these rats was found in the
border, while the nonparticulate super-
t fraction contained appreciable quantities
e cholesterol ester synthetase activity.
er, the retinyl ester hydrolase and syn-
se activities were distributed in all of the
fractions, with the brush border containing
ajor portion of the hydrolase and the non-
culate supernatant fraction more of the
etase activity. On separation of the intes-
contents of rats given 4- ^{14}C-cholesterol
e or retinyl acetate into the micellar and
hases, the micellar phase contained only
erified cholesterol, and the fat phase both
ified and unesterified sterol. Retinyl
s and retinol, on the other hand, were
ibuted in both fat and micellar phases, with
at phase containing higher amounts of retinyl
s and the micellar phase more of retinol.
retinyl acetate was fed, the brush border
contained cholesterol esters. In contrast,
retinyl acetate was fed, the brush border
ined only the acetate at 30 min., and both
cetate and higher esters at 120 min., while
onparticulate fraction of the cell contained
the higher esters of retinol at both the
intervals.

THE EFFECT OF LITHIUM ON INTESTINAL
SUGAR TRANSPORT. (E.) Bihler, I. (U.
oba, Winnipeg, Canada) and S. Adamic.
im. Biophys. Acta 135(3):466-474, 1967.

uptake of hamster small intestine *in vitro*
easured with various replacements for Na in
edium. The basic incubation medium con-
d of 120 mM NaCl buffered with 25 mM Tris
ide-bicarbonate (pH 7.4) and contained, in
ion, the same conc. of K, Ca, Mg, SO_4 and
s the original Krebs-Henseleit bicarbonate
r with which it was isosmotic; modified media were prepared by replacing the NaCl with isosmotic amounts of LiCl, KCl, choline chloride or mannitol, which are subsequently referred to as Li, K, choline and mannitol media, resp. None of the various replacements for Na supported transport against a conc. difference, but sugar equilibration was significantly more rapid in the presence of Li than of mannitol, choline or K. This stimulatory effect of Li was inhibited by 0.5 mM phlorhizin and was observed with 3-O-methyl-D-glucose, D-galactose and α-methyl-D-glucoside, which are all actively transported in the presence of Na, but not with L-fucose and L-arabinose. Mutual inhibition between 3-O-methyl-D-glucose and D-galactose was observed in Li medium, but not in mannitol medium. Li had no effect on the entry of α-aminoisobutyric acid. It is suggested that Li stimulates sugar entry by activating the sugar "carrier" and not by interacting with the Na pump. These results are consistent with the hypothesis of Crane *et al.* that intestinal sugar active transport is mediated by an ion-activated carrier.

10971 D-XYLOSE: ACTIVE INTESTINAL TRANSPORT IN A SODIUM ION SUBSTITUTED LITHIUM MEDIUM. (E.) Faust, R. G. (U. North Carolina Sch. Med., Chapel Hill), J. W. Hollifield and M. G. Leadbetter. Nature (London) 215(5107): 1297-1298, 1967.

Using fed male Sprague-Dawley rats, cannulated everted sacs of jejunum were filled and incubated at 37°C for 1 hr. in 100 ml of gassed (O_2:CO_2, 95:5) Na, Li or K bicarbonate saline soln., at pH 7.4, containing 6.66 mmoles of either D-xylose, D-ribose, L-arabinose or D-arabinose; when Na was replaced, equal molarities of either Li or K were used. Using this method, the final conc. of D-xylose within the mucosa in the presence of Na was almost twice as great as the initial conc. in the incubation medium; the other pentoses had a final mucosal tissue conc. that was similar to the initial medium conc. of 6.66 mmoles. In a $LiHCO_3$ saline medium, D-xylose was also actively transported; no change was observed with the other pentoses. The active transport of D-xylose was not evident when K was substituted for Na. Additional experiments were done in order to compare the active transport of D-xylose in $NaHCO_3$ and $LiHCO_3$ saline, using various inhibitors. Active D-xylose transport in both the Na and Li media was inhibited by phlorhizin, iodoacetic acid and NaF, and 2,4-nitrophenol; oligomycin, an inhibitor of oxidative phosphorylation, was very effective in inhibiting active D-xylose transport in the presence of Na, but was not nearly as effective when Na was replaced by Li. These findings illustrate that the mechanism of active D-xylose transport by mucosa from rat jejunum is similar in either $NaHCO_3$ or $LiHCO_3$ saline. In addition, the energy requirements for this process are similar to those observed for the active intestinal transport of other sugars. The fact that Li can replace Na in the incubation medium is the only apparent difference in the mechanism of active transport of this pentose and other sugars.

10972 THE EFFECT OF DIFFERENT HYDROGEN ION CONCENTRATIONS UPON GLUCOSE ABSORPTION.

(Ger.) Förster, H. (U. Munich, Germany), W. Erdlenbruch and H. Mehnert. Z. Ges. Exp. Med. 144(1):14-23, 1967.

A cannula was inserted into the duodenum from the stomach and a plastic tube inserted into the ileum 2 cm above the cecum in fasted male rats. The small intestine was perfused with 60 ml of fluid which entered the duodenum and left the ileum at a rate of flow of 0.9 ml/min. produced by a roller pump. Polyvinylpyrrolidone (2%) was added to the perfusate to serve as a marker for absorption. The different pH values of polyvinylpyrrolidone and glucose-containing perfusion fluid were obtained by the addition of 2 N HCl or 2 N NaOH. In some tests buffer soln. of glycine and $NaHCO_3$ were used, in others the osmotic pressure was changed with 0.33 M NaCl. After perfusion, segments of the proximal small intestine from 10 animals were prepared for histology. The changes of pH were neutralized by intestinal secretions even when the change resulted from the addition of a buffer pair; only at extreme values did neutralization not occur. The absorption of a 1% glucose soln. hardly varied in a pH range from 3-9.5. Absorption was inhibited only beyond these extremes with visible macroscopic and microscopic structural alterations of the mucosa. In particular the passive uptake of glucose is reduced as H_2O absorption is also reduced. The active component in glucose transport seems relatively insensitive to pH changes.

10973 STUDIES ON TRANSMURAL POTENTIALS IN VITRO IN RELATION TO INTESTINAL ABSORPTION.

IV. PHLORIZIN-SUGAR INTERACTIONS IN RAT GUT.

(E.) Lyon, I. (Chicago Med. Sch., Ill.). Biochim. Biophys. Acta 135(3):496-506, 1967.

A simple and sensitive system is described for measurement of short-circuit current across the wall of everted sacs of rat small intestine. With this system, phlorhizin-dependent changes in current, and in transmural potential, were measured and appeared to be saturable functions of the phlorhizin conc. in the medium. These changes in short-circuit current and potential difference, by analogy was similar saturation effects upon changes in current and transmural potential induced by actively transported sugars, may be interpreted in terms of an interaction of Na and phlorizin with a mobile carrier in the brush border membrane of the intestinal epithelial cell. By extrapolation from plots of the reciprocal of the transmural potential or the reciprocal of the changes in current against the reciprocal of the phlorhizin or sugar conc., apparent Michaelis constant and inhibitor constant values for phlorhizin, the latter determined against glucose and several of its analogs, were estimated. The differential effects of t
Na conc. in the medium upon the apparent Michaelis constant and inhibitory constant values suggest that phlorhizin may enter the cell by 2 modes of interaction with the carrie
1 mode of entry, specified by inhibitor consta
values, is Na-sensitive and may be the consequ
of interactions of glucose moiety with the sugar-binding site of the carrier; the other mode of entry, specified by Michaelis constant
values, is relatively Na-insensitive, and may
depend upon interactions between the carrier a
the aglycone moiety of phlorhizin. The ratio
apparent Michaelis constant for a given sugar
the apparent inhibitor constant of phlorhizin against that sugar remained essentially unchan
irrespective of the Na conc. In addition, Michaelis constant/inhibitor constant ratios f
2 or more structurally-related sugars seem to allow for sharper discrimination between their
affinities for the carrier than can be inferre
from sugar apparent Michaelis constant values alone.

10974 HYPOTHESIS FOR THE INTERACTION OF PHLORIZIN AND PHLORETIN WITH MEMBRAN

CARRIERS FOR SUGARS. (E.) Alvarado, F. (Rutg
Med. Sch., N. J.). Biochim. Biophys. Acta 135(3):483-495, 1967.

Using 6-deoxy-D-glucose and D-xylose as substrates, it was found that phlorhizin, but not
its aglycon, phloretin, is a fully competitive
inhibitor of sugar active transport in the ham
ster small intestine. The results indicated that 1) phlorhizin competes with glucose and i
analogs for a common membrane binding site; an
2) phloretin inhibits sugar transport alloster
cally through binding to a different, but closely associated, binding site. In order to
explain these findings, a kinetic model was co
structed in which the carrier is assumed to possess 2 different sites, namely a sugar- and a phenol-binding site. Phlorhizin binds simultaneously to both of these sites. The synergistic effect of this double binding causes the overall affinity of phlorhizin for the sugar carrier to be 3-4 orders of magnitud
higher than that of the physiological substrat
glucose. Phloretin binds only to the phenol s
The differences among tissues in their relativ
responses to phlorhizin and phloretin are attributed to differing spatial relationships between the sugar site and the phenol site.

10975 EFFECTS OF DIETARY IRON LEVEL ON GUT IRON LEVELS AND IRON ABSORPTION IN T

RAT. (E.) Pearson, W. N. (Vanderbilt U. Med. Sch., Nashville, Tenn.), M. Reich, H. Frank and
L. Salamat. J. Nutr. 92(1):53-65, 1967.

The hypothesis that the Fe content of the intestine is of critical importance in determi
ing the rate of Fe absorption was investigated in Sprague-Dawley rats. The Fe content of the

RPTION
ntestine was found to vary with the Fe con-
of the diet, but the relationship was not
r. The more proximal sections of the intes-
were more sensitive to dietary Fe level
the distal portions. Rats fed stock rations
uch lower proximal intestinal Fe levels
rats fed purified diets of lower Fe content.
e content of the intestine appeared to
ence, within limits, the absorption of ^{59}Fe
an isolated intestinal loop. When rats
changed from a high Fe diet to a low Fe
a steady depletion of Fe from the intestine
ccompanied by an increase of Fe absorption
was max. on the third-to-fifth day after
hange of diet. In the reverse experiment,
sorption was almost immediately depressed
mitant with the elevation of the intestinal
vel. The Fe content of the mucosa did not
r to influence the entrance of the test dose
into the mucosa; instead, the major point
cosal regulation appeared to be the transfer
from the mucosa to the blood supply.
re of a large dose of Fe placed in the
um to influence immediately the absorption
Fe from a duodenal loop indicates that
mucosal (possibly hormonal) control of Fe
ption is lacking or minimal.

EFFECT OF STARVATION AND PROTEIN
DEPLETION ON FERROKINETICS AND IRON
PTION. (E.) Conrad, M. E. (Walter Reed
Inst. Res., Washington, D. C.), A. L. Foy,
Williams and W. H. Knospe. Amer. J. Physiol.
):557-565, 1967.

ation and protein-deficient diets caused
ased absorption of Fe in male albino rats.
vations at intervals after onset of fasting
n rats fed various quantities of protein
sted that the changes in Fe metabolism were
o depressed erythropoiesis and retarded
h. The protein-deficient diets were similar
e food consumed by "starch eaters" and
itants of rice-eating countries (except that
contained adequate amounts of added Fe);
diets caused a normocytic, normochromic
a, with decreased absorption which was
ed to diminished erythropoiesis and not to
luminal intestinal factors. The rats tried
-establish and maintain a normal body conc.
by decreased absorption and increased excre-
of Fe; the decreased Fe absorption was not
panied by an increased Fe content or conc.
e duodenal mucosa. In starved animals, how-
increased amounts of dialyzable Fe was
porated into the duodenum from body stores.
ugh the total quantity of Fe in the intes-
mucosa may be unimportant, it is suggested
the source and chemical form of Fe may be
nificant factor in the regulation of Fe
ption.

IRON CONTENT OF DUODENOJEJUNAL VILLI.
IRON ABSORPTION FROM THE VIEWPOINT OF
LOGY. (Fr.) Cattan, D. (Bichat Hosp., Paris),
C. Marche, G. P. Jori and C. Debray. Nouv. Rev. Franc. Hemat. 7(2):259-270, 1967.

In 9 men and 1 woman biopsies were taken of the gastric, duodenal, and jejunal mucosa and puncture biopsy of the liver, before and after p.o. admin. of Fe. Tissues were prepared for histology and sections were stained with Prussian blue for Fe determination. The Fe deposited in the apical cells, varied from villus to villus and was quite unequal in adjacent cells. The general epithelial cells contained only minute amounts of Fe and seemed incapable of the rapid uptake and transport of Fe from normal p.o. doses. The macrophages, subepithelial, pericapillary, and in the corium, had the greatest local store of Fe. These cells are in constant interchange of p.o. Fe from the apical cells, plasma Fe, and Fe from hemoglobin. It has been proved by radioactive Fe that RBC are destroyed in the intestinal mucosa; the radioactivity was found in the macrophages. The greater the amount of Fe stored in macrophages, the less p.o. Fe absorbed in the intestine. It is thought that macrophages release Fe directly into the plasma as do other cells of the reticuloendothelial system.

10978 EXPERIMENTAL STUDIES ON THE INFLUENCE OF CHRONIC ALCOHOL INGESTION ON ABSORPTION OF IRON IN THE SMALL INTESTINE OF RATS IN VITRO. (Pol.) Hoszowska-Owczarkowa, H. (Inst. Pharmacol., Acad. Med., Szczecin, Poland), L. Samochowiec and J. Wójcicki. Acta Physiol. Pol. 17(3):435-439, 1967.

Experimental alcoholism in white rats did not influence the absorption of ferrous gluconate in the small intestine according to in vitro studies conducted by a modified Wiseman method. The mean absorption of Fe by the small intestine from 11 controls was 71.78 µg with a mean deviation of 13.53 µg, whereas the absorption by the small intestine from the alcoholic rats was 67.04 µg, with a mean deviation of 18.93 µg. In contrast, the in vitro absorption by the small intestine of nutrient fluid was retarded in the alcohol-treated animals where the absorption was 0.9 ml (mean deviation, 0.57 ml) as compared to 2.3 ml (mean deivation 0.88 ml) with the control rats.

10979 LARGE AND SMALL DOSES OF ASCORBIC ACID IN THE ABSORPTION OF FERROUS IRON. (E.) Lee, P. C. (Mayo Clin., Rochester, Minn.), J. R. Ledwich and D. C. Smith. Canad. Med. Ass. J. 97(4):181-184, 1967.

Absorption of ferrous Fe was studied in 40 fasting, nonanemic subjects (22 men, 18 women; 19-80 yr. old.); none were under treatment for Fe deficiency and none had hemoglobin values below 75% (11.0 g/100 ml). Three procedures were used. In the first, after obtaining blood for an initial serum Fe determination, 200 mg, p.o. ferrous sulfate, was admin.; then 4 serum Fe estimations using the Ramsay method were made at hourly intervals. The method of study used in the other 2 procedures was similar to the first, except that in the second 50 mg of ascorbic acid was admin. with the ferrous sulfate and in the third, 1 g of ascorbic acid was admin. with the ferrous sulfate. The procedures were performed at 4-day intervals in each subject, and their sequence was randomized. No significant differences were found between the first 2 procedures. Higher elevations in serum Fe were found when ferrous sulfate was admin. with 1 g of ascorbic acid, suggesting that this dose, but not a dose of 50 mg, significantly enhances the absorption of ferrous sulfate.

10980 THE RELATIONSHIP BETWEEN DUODENAL MUCOSAL IRON CONCENTRATION AND IRON ABSORPTION IN HUMAN SUBJECTS. (E.) Allgood, J. W. (Washington U. Sch. Med., St. Louis, Mo.) and E. B. Brown. Scand. J. Haemat. 4(3):217-229, 1967.

Non-heme Fe conc. of duodenal mucosa obtained by peroral capsule biospy were determined in normal, Fe-deficient and Fe-overloaded human subjects. Intestinal Fe conc. of normal subjects did not differ significantly from those of the Fe-deficient or Fe-overloaded subjects. No significant variation was detected in Fe conc. of mucosa obtained from various anatomical segments of duodenum removed at autopsy. Intestinal non-heme Fe conc. showed no significant correlation with simultaneous measurements of serum Fe conc. nor with radio-Fe absorption in a group of 25 patients (including normal, Fe-deficient and Fe-overloaded subjects). Radio-Fe absorption was correlated significantly with the severity of anemia, but not with serum Fe conc. or percentage transferrin saturation. Failure to confirm prior studies in animals indicates that species differences exist in the regulation of gastrointestinal Fe absorption and underscores the need for additional studies of the control Fe absorption in man.

10981 COMPARISON BETWEEN THREE RADIOISOTOPE METHODS FOR MEASURING IRON ABSORPTION. (E.) Lunn, J. A. (Roy. Infirm., Edinburgh, Scotland), J. Richmond, J. D. Simpson, J. D. Leask and P. Tothill. Brit. Med. J. 3(5561):331-333, 1967.

A simple inexpensive whole-body counting technic for Fe absorption in which radioactivity was measured in 3 positions with the patient prone and supine is described. This method, together with the "fecal recovery" and double-isotope methods of determining Fe absorption, were compared over a wide range of hemoglobin level, serum Fe and stainable marrow Fe in 17 patients. Using the first method, only 2 measurements on the patient were required, each taking approx. 15 min. This method gave results which correlated well with the double isotope method
in 16 patients who showed a wide range of hemc
globin level, serum Fe and stainable marrow Fe
Although a good correlation was obtained in th
whole-body counting method between the lying a
sitting positions, the estimate of absorption
for the sitting posture was much higher than f
the lying position in 4 patients and exceeded
100% in 2. The poorer agreement in the sittir
position was presumably due to redistribution
effects. The fecal recovery method of Fe
absorption, which was used simultaneously,
showed poor agreement with the whole-body coun
ing and double isotope technics; this discrepa
is believed to have been due to incomplete stc
collections.

10982 THE EFFECT OF TRYPSIN, CHYMOTRYPSINO
CHYMOTRYPSIN AND AMYLASE ON IRON
ABSORPTION. (Ger.) Dietze, F. (U. Clin.,
Berlin), G. Brüschke, A. Rückert, F. H. Schulz
I. Stokov and S. Wuttke. Deutsch. Gesundh.
22(28):1304-1305, 1967.

These crystallized trypsin, chymotrypsinogen,
chymotrypsin and amylase (6 Kunitz U/mg) were
used in various p.o. dosages (2-8 mg/kg) to
study their effect upon the absorption of ferr
iron (1.5 mg/kg p.o.) taken without enzyme or
followed in 5 min. by an enzyme. Serum Fe con
was determined each hr. for 3 hr. After 3 hr.
the normal range of serum Fe was 250-320 µg% a
290 µg%; with 2 mg trypsin/kg serum Fe was
220 µg%; 4 mg trypsin/kg, serum Fe 195 µg%; 8
trypsin/kg, 160 µg% of serum Fe. Chymotrypsinogen, 2 mg/kg, reduced serum Fe to 200 µg%
and 4 mg/kg to 115 µg%. The reduction of seru
Fe was somewhat less with chymotrypsin which,
a dose of 8 mg/kg, reduced serum Fe after 3 hr
to 115 µg%. These reductions below the normal
values were clearly due to inhibited absorptio
Amylase had no effect on the absorption of Fe.

10983 BICARBONATE-INDUCED IRON COMPLEXES A
IRON ABSORPTION: ONE EFFECT OF
PANCREATIC SECRETIONS. (E.) Bemjamin, B. I.
(Walter Reed Army Inst. Res., Washington, D. C
S. Cortell and M. E. Conrad. Gastroenterology
53(3):389-396, 1967.

Male guinea pigs were fed a standard laborator
diet containing 12 mg of Fe/100 g dry wt.; 1 group of animals were made Fe-deficient by repeated phlebotomies and a second group was Fe-loaded by i.m. inj. of dextran-Fe. Fe absorption studies were done on these animals,
as well as on animals that received secretin,
or 25 Crick U i.p., to stimulate pancreatic bicarbonate secretion. The effect of dilute (0.015 M) and conc. (0.5 M) $NaHCO_3$ on Fe absor
tion was studied. Addition of $NaHCO_3$ to Fe soln. produced both soluble macromolecular Fe chelates and Fe precipitates, and caused decreased absorption of test doses of Fe by normal guinea pigs. Similar physicochemical changes occurred when Fe soln. were added to

enal secretions. Likewise, inj. of normal
als with secretin reduced Fe absorption.
e findings suggest that decreased secretion
icarbonate by the pancreas in the various
romes of pancreatic insufficiency may be
rtant in causing increased absorption of Fe.
s unlikely that this phenomenon causes
ve Fe overloading because bicarbonate did
significantly affect Fe absorption by Fe-
ed or Fe-deficient animals.

EFFECT OF PANCREAS EXTRACT ON Fe^{59}
ABSORPTION BY ANEMIC RATS. (E.)
y, M. J. (U. Minnesota, Minneapolis) and
ein. J. Lab. Clin. Med. 70(3):361-364,

e Sprague-Dawley rats (47) were made anemic
eding an Fe-free evaporated milk with
in supplements, deionized water and a
ement of 18.2 ppm of Cu as a copper sulfate
(used to avoid Cu deficiency); in addition,
were bled from a tail vein at a rate of
wk. for 6 wk. At the end of this period,
rat was given a p.o. test dose of 0.25 μc of
ferrous citrate with 0.25 mg of ferrous
te as carrier in a total vol. of 0.7 ml.
nemic rats were then divided into 3 groups:
1, the control anemic group, was fed
rated milk; Group 2 was fed undiluted pancreas
r, 2 g/rat/day, mixed with evaporated milk;
roup 3 was fed bromelain 2 g/rat/day in
ilk (bromelain was used as a control en-
. The absorption of ^{59}Fe was studied be-
and after the feeding of pancreas extract
romelain. No significant depression of Fe
ption resulted from feeding pancreas powder,
here was a significant depression in rats
he control substance, bromelain. These
ts do not support previous suggestions that
eatic extract specifically depresses the
ption of Fe. The effect of bromelain was
triking in spite of its significance,
sting that this was most likely a nonspecific
t caused by weak binding with the metal.

INTESTINAL SPLITTING OF OLIGOSAC-
CHARIDES. (Ger.) Täufel, K. (Inst.
, Potsdam-Rehbrucke, Germany), W. Krause,
ttloff and R. Maune. Z. Ges. Exp. Med.
):54-66, 1967.

ed 10-cm sacs of the rat small intestine,
d with balanced physiological saline, tied,
eighed were placed in a definite vol. of
ced physiological saline (containing the
to be tested). The sugar in the outer
was determined at the beginning of a 1-hr.
and again at the end of this period when
was also determined in the fluid within the
Sugar, introduced in soln. *in vivo* into
tinal loops with intact circulation, was
mined in the portal blood, and sugar soln.
ated into the intact animal was determined
e urine. The activities of α-amylase,
dextranase, and α-glucosidase in the intestinal segments were established. Analysis of the saccharides was by quantitative paper chromatography. Different oligosaccharides (maltose, sucrose, a mixture of malto-oligosaccharides, a mixture of isomalto-oligosaccharides, lactose, lactulose, raffinose, stachyose and verbascose) were tested with respect to their absorption as intact components, and in terms of intestinal carbohydrase activity. Nonhydrolyzed sugars passed through the intestinal wall in increasing amounts as the enzyme activity of the segment decreased; the amount of sugar passing was extremely small. After p.o. or i.p. admin. the tested oligosaccharides (except maltose and malto-oligosaccharides) were found in the serum of the portal vein and in the urine in small quantities; this supports the *in vitro* studies. The passage seems to be an inverse function of molecular size. The liver and kidney of the rat have extremely low or no carbohydrase activity; consequently, sugars which are absorbed unchanged are excreted unchanged in the urine.

10986 EFFECT OF PEPSIN ON THE ABSORPTION OF FOOD VITAMIN B$_{12}$ AND IRON. (E.) Schade, S. G. (U. Wisconsin Med. Sch., Madison) and R. F. Schilling. Amer. J. Clin. Nutr. 20(6):636-640, 1967.

In vitro peptic digestion did not alter the absorption of egg vitamin B$_{12}$ or Fe in 10 patients with pernicious anemia. Following ingestion of eggs from chickens which had been inj. with B$_{12}$, Co^{57} and ^{59}Fe, the mean of B$_{12}$ excretion in the stool of pernicious anemia patients was 76% with pepsin-treated eggs (addition of 1 g of pepsin to egg homogenate) and 81% with nonpepsin-treated eggs. The difference between these 2 means is only significant at the 0.15 level of probability, however, the mean excretion of B$_{12}$ in the control patients was 61% which is significantly different in both groups. The mean of ^{59}Fe excretion in pernicious anemia patients with pepsin-treated eggs was 89% and with non-pepsin-treated eggs, 86%. The mean excretion in the control patients was 88%. Studies made on the dialyzability of egg B$_{12}$ and Fe showed that pepsin releases B$_{12}$ for dialysis, whereas it had little effect on the dialyzability of Fe. This would indicate that the peptic treatment of the eggs enhanced the dialyzability of B$_{12}$, thus increasing the absorption somewhat.

10987 SOLUBILIZATION OF SUGARS IN NON-POLAR SOLVENT BY INTESTINAL LIPIDS: POSSIBLE RELATION TO MEMBRANE TRANSPORT. (E.) Baker, R. D. (U. Texas Med. Branch, Galveston). Texas Rep. Biol. Med. 25(2):223-239, 1967.

Total lipids were extracted from adult male Swiss mice, Yale strain, small intestine and used to study the solubilization of sugars in nonpolar solvent. Although monosaccharides are insoluble in pure nonpolar solvents, they could be solubilized by mixed lipids extracted from the mouse small intestine. An av. of 8.3 molecules of D-galactose could be solubilized in hexane/molecule of phospholipid. Stoichiometric studies indicated that solubilization was not due to a formation of a specific chemical complex between sugar and phospholipid, but was due to incorporation into micelles formed by amphophilic lipids. An apparent critical micelle conc. was detected at a phospholipid conc. of approx. 3×10^{-6} M. This phenomenon did not indicate the presence, in lipid extracts, of a specific membrane carrier, as had been suggested by previous authors. However, if sites (evidence for which was found) existed in the lipid phase of plasma membranes which correspond in structure to the hydrophilic interior of these micelles, such sites could incorporate sugar molecules and might be utilized in transmembrane passage. The solubilization of D-galactose in hexane was strongly inhibited by phlorhizin, an observation that may be relevant to the mechanism of phlorhizin action on the intestine. Max. solubilization was significantly different for 3 different sugars, but the order of preference was not similar to that for intestinal absorption. Mannose was solubilized significantly better than galactose, mannitol and urea; mannitol and 3-o-methylglucose were both solubilized significantly better than were galactose and urea. Filtration of hexane soln. through highly retentive paper markedly decreased the solubilization of D-mannitol and urea, without affecting that of D-galactose, 3-o-methyl-D-glucose and D-mannose.

10988 STUDIES IN VITRO OF THE PASSAGE OF SERUM PROTEINS ACROSS THE INTESTINAL WALL OF YOUNG RATS. (E.) Bamford, D. R. (U. Coll. North Wales, Bangor). Proc. Roy. Soc. [Biol.] 166:30-45, 1967.

The everted ileal sacs of 18-day-old rats were used as in vitro preparations to determine whether such preparations would be useful in studying the transport of γ-globulin. Such sacs were seen to remain viable and functional for at least 1 hr. when incubated at 37°C under aerobic conditions. When the transport of ^{131}I-labeled γ-globulin was examined in such a system it was seen that significantly more of the homologous γ-globulins were transported to the serosal compartment than either of the heterologous molecules. There was an increase in the conc. of free iodide in the final mucosal fluid. This was due to the degradation of labeled protein to small nonprecipitable U. γ-Globulins were transmitted differently from the mucosal to the serosal fluid depending upon the species. An increase in O_2 consumption of the tissues occurred during protein transport.

10989 EVIDENCE FOR A SPECIAL TYPE OF BICARBONATE TRANSPORT IN THE ISOLATED COLONIC MUCOSA OF BUFO ARENARUM. (E.) Lew, V. L. (Nat. Inst. Health, Haedo, Argentina) and N. J. Carlisky. Biochim. Biophys. Acta 135(4):793-796, 1967.

The existence of at least 2 different component
of the short circuit current in the isolated
colonic mucosa of the South American toad, Buf
arenarum was demonstrated. Females of between
250 and 350 g wt. were used within the first 2
wk. of captivity. At this time the observed
difference between the short circuit current a
the Na ion net·flux was max. Data from the pr
study clearly demonstrate the existence of a
bicarbonate transport in the short circuit cur
although no quantitative evaluation of its participation could be made. The present finding
not allow a conclusion as to whether the prima
process is the passage of bicarbonate from the
cell to the mucosal side or of H ion in the opposite direction.

10990 STUDIES ON IRON ABSORPTION. VI. TH
EFFECT OF BILE AND PANCREATIN ON THE
ABSORPTION OF IRON. (E.) Sörensen, E. W. (U.
Bergen, Norway). Acta Med. Scand. 181(6):707-
1967.

The effect of bile and pancreatin on Fe absorp
from the intestine was studied in anemic patie
in Fe-deficient and in non-Fe-deficient rats.
the 20 anemic patients, the enzyme preparation
(0.32 g dehydrated bile, 1.2 g pancreatin) wer
given together with Fe doses (300 mg Fe^{++}) and
standard meal. With the applied doses, neithe
the enzyme preparations had a significant effe
on Fe absorption. When Fe was given together
with a normal stock diet to non-Fe-deficient r
no effect of pancreatin (0.2 g) was found, and
a further addition of ascorbic acid or alcohol
had no increasing effect on Fe absorption. Pa
creatin inhibited a demonstrated increasing ef
which a carbohydrate-rich (0.5 g glucose), and
to a smaller degree, a fat-(1 g 35% cream) or
protein-(1 g skimmed milk powder)-rich meal ha
on the Fe absorption. In the nonanemic rats,
(0.16 g dehydrated bile) had a reducing effect
on the absorption of Fe; this occurred with ea
of the meals that Fe was given with (normal st
diet, carbohydrate, fat and protein). In rats
made Fe-deficient by means of repeated bleedin
and feeding of an Fe-poor diet, the Fe absorpt
was considerably higher than in the non-Fe-def
ient group. Pancreatin had a reducing influen
on the Fe absorption independent of the type o
meal given (normal stock diet, carbohydrate, f
or protein). Bile also had a significant redu
ing effect, except when the Fe was given toget
with carbohydrate. These results support the
concept that the pancreas produces a substance
that may be able to inhibit Fe absorption. In
addition, it is concluded that both bile and p
creatin have a reducing effect on Fe absorptio
rats.

10991 STUDIES ON IRON ABSORPTION. VII. I
ABSORPTION IN RATS WITH CARBON TETRA
CHLORIDE (CCL_4) INDUCED DAMAGE AND CIRRHOSIS O
THE LIVER. (E.) Sörensen, E. W. (U. Bergen,
Norway). Acta Med. Scand. 181(6):739-746, 196

absorption was studied in 3 groups of rats ex-
ed to CCl$_4$ vapor for 1 min./day during 45, 70
110 days, resp.; the animals were fed an Fe
e plus 1 g normal diet and 1 ml water or 1 g
mal diet and 1 ml of a H$_2$O-96% ethanol mixture.
addition, the effects of bile (0.16 g dehydrated
e) and pancreatin (0.2 g) on Fe absorption were
essed. Histologically, there were gradually
reasing signs of liver cell degeneration, ac-
panied in the 110-day group by a considerable
rease of connective tissue with a nodular ar-
gement of the liver cells. Increased amounts
Fe deposits were seen in the liver and pancreas.
other signs of pathological changes were found
the duodenum, spleen or pancreas. Fe absorp-
on was significantly reduced in all series after
CCl$_4$ treatment. The expected increasing ef-
t of alcohol was present, but this effect was
ufficient to increase the amount of absorbed
to the level found before CCl$_4$ treatment. Both
ncreatin and bile had a significant increasing
fect on Fe absorption; pancreatin doubled the
rcentage of absorbed Fe, whereas the effect of
e was somewhat less. This study offers strong
dence that liver injury or cirrhosis cannot
d to increased Fe absorption.

11009 INTRACELLULAR TRANSPORT OF SECRETORY PROTEINS IN THE PANCREATIC EXOCRINE CELL. I. ROLE OF THE PERIPHERAL ELEMENTS OF THE GOLGI COMPLEX. (E.) Jamieson, J. D. (Rockefeller U., New York City) and G. E. Palade. J. Cell Biol. 34(2):577-596, 1967.

Electron microscopic radioautography of guinea-pig pancreatic exocrine cells established that secretory proteins are transported from the elements of the rough-surfaced endoplasmic reticulum to condensing vacuoles of the Golgi complex, possibly by small vesicles located in the periphery of the complex. In order to more clearly define the role of these vesicles in the intracellular transport of secretory proteins, the secretory cycle of the guinea pig pancreas was studied by cell fractionation procedures applied to pancreatic slices incubated in vitro. Such slices remain viable for 3 hr., and incur minimal structural damage during this period. Their secretory proteins can be labeled with radioactive amino acids in short, well-defined pulses which, followed by cell fractionation, facilitates a kinetic analysis of transport. In order to determine the kinetics of transport, sets of slices were pulse-labeled for 3 min. with leucine-^{14}C and incubated for further +7, +17 and +57 min. in chase medium. At each time, smooth microsomes (peripheral elements of the Golgi complex) and rough microsomes (elements of the rough endoplasmic reticulum) were isolated from the slices by density gradient centrifugation of the total microsomal fraction. Labeled proteins appeared initially (end of pulse) in the rough microsomes and were transferred subsequently during incubation in chase medium to the smooth microsomes, reaching a max. conc. in this fraction after +7 min. chase incubation. Labeled proteins later left the smooth microsomes to appear in the zymogen granule fraction. These findings provide direct evidence that secretory proteins are transported from the cisternae of the rough endoplasmic reticulum to condensing vacuoles through the small vacuoles of the Golgi complex.

11010 INTRACELLULAR TRANSPORT OF SECRETORY PROTEINS IN THE PANCREATIC EXOCRINE CELL. II. TRANSPORT TO CONDENSING VACUOLES AND ZYMOGEN GRANULES. (E.) Jamieson, J. D. (Rockefeller U., New York City) and G. E. Palade. J. Cell Biol. 34(2):597-615, 1967.

In a previous study, direct evidence was obtained that secretory proteins are transported from the cisternae of the rough endoplasmic reticulum to condensing vacuoles of the Golgi complex by small vesicles located in the periphery of the complex. Since condensing vacuoles ultimately become zymogen granules, this phase of the secretory cycle was studied in pulse-labeled slices. A zymogen granule fraction was isolated by differential centrifugation from guinea-pig pancreatic slices at the end of a 3-min. pulse with leucine-^{14}C and after varying times of incubation in chase medium. At the end of the pulse, few radioactive proteins were found in this fraction; after +17 min. in chaser, its proteins were half-max. labeled; they became max. labeled between +37 and +57 min. Paralle electron microscopic radioautography of intact cells in slices pulse-labeled with leucine-3H showed that zymogen granules became labeled, a the earliest, at +57 min. post-pulse. It was assumed that the discrepancy between these 2 s of results was due to the presence of rapidly labeled condensing vacuoles in the zymogen gra fraction. In order to clarify this assumption electron microscopic radioautography was performed on sections of zymogen granule pellets isolated from slices pulse-labeled with leucin and subsequently incubated in chaser. The results showed that the early labeling of the zymogen granule fractions was due to the prese of highly-labeled condensing vacuoles among th components of these fractions.

11011 GASTRIC SECRETION OF ACID AND INTRIN FACTOR DURING HISTAMINE INFUSION IN 14 CASES OF DUODENAL ULCER. (E.) Doteval1, G (Sahlgrenska Hosp., Goteborg, Sweden), A. Wala and A. Weinfeld. Scand. J. Haemat. 4(3):169-1 1967.

The secretion of HCl and of intrinsic factor w studied in 14 subjects (all men) with chronic duodenal ulcer before and during six 15-min. periods of i.v. histamine (0.0021-0.0354 mg/kg 15 min.) infusion. The quantity of infused histamine was increased with each 15-min. peri The vol. of gastric juice increased successive during the first 4 periods and was max. and equal in the last 3 periods of increasing histamine stimulation. The secretion of HCl increased steadily during the increasing rate histamine infusion, reaching a max. and equal output in the final 2 periods. The conc. of intrinsic factor was max. in the first period and decreased steadily in the following period of histamine stimulation. The output of intrinsic factor was max. during the first 3 periods and decreased during the following per in spite of increasing rate of histamine infusion. Since the vol. of gastric juice was max. and equal during the final 3 periods, the fall in intrinsic factor conc. was more marked than the decrease in its output. The conc. of intrinsic factor in the final period was lower than basally. These results indicate that histamine causes a washout of stored intrinsic factor. The output of intrinsic factor, howev was still significantly higher than basally, even 75-90 min. after histamine infusion had started. This fact could be due to a late was out mechanism or to a stimulation of intrinsic factor production and secretion.

12 ANTRAL ACTIVITY AND SYMPTOM PERIODICITY IN DUODENAL ULCERATION. (E.)

estin, L. R. (Bristol Roy. Infirm., England).
8(4):318-324, 1967.

3 groups of subjects, the 3 main factors olved in gastric secretion were studied: 1) ral response to mechanical stimulation; 2) ral response to chemical stimulation; and 3) x secretory capacity of the parietal cell ulation. The subjects studied included Group 5 patients with no gastrointestinal disorder; up 2, 5 patients with quiescent duodenal eration; and Group 3, 10 patients with active denal ulceration. A modification of a tube lumen) devised by Marks to study secretion er Polya gastrectomy was used. Histamine was n. i.v. at the rate of 5 mg/hr., and a meat h used consisted of a standard Bovril soln. pared by diluting 15 ml of the commercial centrate with H_2O to a total of 400 ml and at its natural pH of 5.5. Normal and escent duodenal ulcer patients showed similar ral activity, but this was increased in the ent with an active duodenal ulcer. Hourly put of secretion in the active ulcer group in ponse to mechanical stimulation was higher n the hourly output to chemical stimulation normal subjects. Antral activity was increased ing periods when exacerbation may be asso- ted with changes in cholinergic tone. It is gested that the episodic nature of duodenal eration depends on variations in antral activity, that healing of an ulcer occurs when the ponse to antral stimulation by food produces arietal cell output of less than 15 mEq/hr.; this respect, there is no difference between called hyposecretors and hypersecretors.

13 SECRETORY RESPONSE OF THE HUMAN PANCREAS TO CONTINUOUS INTRAVENOUS USION OF PANCREOZYMIN-CHOLECYSTOKININ (CECEKIN).

) Banwell, J. G. (Gen. Hosp., Birmingham, land), B. E. Northam and W. T. Cooke. Gut):380-387, 1967.

secretory response of the human pancreas to tinuous i.v. infusion of a pancreozymin- lecystokinin compound (Cecekin) was determined 3 normal subjects (22-65 yr. old) and in ients with various gastrointestinal disorders; latter included 3 with chronic pancreatitis, ith acute pancreatitis, 2 with chronic lecystitis and cholelithiasis (1 before and 1 er cholecystectomy), 4 with adult celiac ease, 1 with tropical sprue in remission, 2 h hepatic cirrhosis, 1 with diarrhea of unknown gin, 1 with diabetic diarrhea, and 1 with the nkhite-Canada syndrome. The pancreozymin- lecystokinin preparation was infused in a ilar manner to secretin at rates sanging from 312-0.5 Harper U pancreozymin/kg/min. Amylase put in basal collections in normal subjects ged from 700-2780 U/min.; a max. amylase out- was obtained in normal subjects in response infusion of the preparation. The 3 patients with chronic pancreatitis had very low max. amylase outputs (24, 12 and 105 U/min., resp.); the patient with postacute phase of acute pancreatitis had a max. response in the normal range (5,350 U/min.); both patients with chronic cholecystitis had normal amylase responses. Of the 4 patients with adult celiac disease, 2 had a max. amylase output within normal range, and 2 had significantly reduced levels of amylase output. The patient with tropical sprue had a low max. amylase output; 1 patient with hepatic cirrhosis had a low amylase output and the other had a normal response. The patient with diarrhea of unknown origin had a subnormal response; the subject with diabetic diarrhea had a low amylase output and the Cronkhite-Canada syndrome patient had a normal max. response. The amylase output after pancreozymin inj. during the secretin-pancreozymin test was lower than the max. amylase output with the pancreozymin-cholecystokinin preparation. All 3 patients with chronic pancreatitis showed no significant elevation in amylase output on pancreozymin stimulation. The protein content of duodenal fluid was not a satisfactory measure of the total amylase output. It is concluded that the secretory response of the human pancreas to continuous i.v. infusion of pancreozymin-cholecystokinin provides an accurate measurement of max. enzyme secretory capacity of the pancreas and eliminates errors due to "wash-out" of amylase.

11014 DIVERSION OF PANCREATIC JUICE ON GASTRIC AND PANCREATIC RESPONSE TO A MEAL STIMULUS. (E.)

Cooke, A. R. (VA Ctr., Los Angeles, Calif.), D. L. Nahrwold and M. I. Grossman. Amer. J. Physiol. 213(3):637-639, 1967.

Three dogs were prepared with a vagally-denervated pouch of the oxyntic gland area (Heidenhain) and a permanent pancreatic fistula; gastric and pancreatic secretion were stimulated by feeding of 250 g of proprietary dog food. Three types of experiments were made in randomized order: 1) the duodenal fistula was not opened so that pancreatic juice drained into the duodenum; 2) all the pancreatic juice was collected every 15 min.; and 3) pancreatic juice was collected every 15 min., and most was then immediately returned to the duodenum. Exclusion of pancreatic juice resulted in a higher acid output from the Heidenhain pouch, and an increase in vol. rate of secretion and bicarbonate output from the pancreas; these effects were abolished by reinstilling pancreatoc juice into the duodenum. Peak bicarbonate output and peak vol. rate of secretion when pancreatic juice was replaced was approx. 60% of that obtained when all of the pancreatic juice was diverted; this can be partially explained by assuming that the presence of pancreatic juice in the duodenum helps to keep the pH neutral, so the secretin mechanism is not fully activated.

11015 MEMBRANE DISCONTINUITIES AND SECRETORY GRANULE FORMATION IN RABBIT PANCREATIC ACINAR CELLS. (E.) Shapiro, S. H. (Jewish Chronic Dis. Hosp., Brooklyn, N. Y.) and S. S. Lazarus. Exp. Molec. Path. 6(3):320-334, 1967.

In osmium tetroxide-fixed (New Zealand white) rabbit (both sexes) pancreatic acinar cells, granules were found ranging in density from electron opaque to electron-lucent. Many of the less dense prozymogen granules were discontinuously limited by smooth membrane in the form of an incomplete band or separated curvilinear segments. Often small, smooth membrane-bound vesicles were found in close association with the granule limiting membrane at points of interrupted limiting membrane. Some small vesicles appeared to originate in the centrosphere region from transition elements of rough and smooth endoplasmic reticulum at the forming face of the Golgi complex, or from the broadened ends of flattened Golgi saccules. Smooth-membraned portions of the endoplasmic reticulum were noted within the granule matrix near membrane-less points of the granule perimeter. Prozymogen granules appeared to form by dilatation and separation of Golgi vacuoles, and/or by delimitation of circumscribed areas of matrix and confluence of small vesicles. Vesicles deriving either from endoplasmic reticulum or Golgi complex seemed to contribute to the formation of the secretory granule and its limiting membrane. Discontinuities in granule limiting membrane were also noted after fixation by permanganate, osmium drip or osmium tetroxide with added $CaCl_2$; this indicated that the membrane discontinuities were not artifactual.

10116 INHIBITION OF VAGALLY STIMULATED GASTRIC SECRETION AFTER MUCOSAL MAST CELL DEGRANULATION. (E.) Hirvonen, J. (U. Helsinki), V. Kamppuri and T. Räsänen. Acta Physiol. Scand. 70(2):236-240, 1967.

Total vagotomy was done on male Sprague-Dawley rats, and the peripheral end of the vagus nerve was electrically stimulated for 1 hr. after closing the ventricle with a Shay ligature; controls were operated upon in an identical manner, but were not stimulated. The mast cells in the gastric mucosa were degranulated with dexamethasone admin. i.m. in 1 group of rats. After stimulation, the gastric fluid was collected, and its vol., pH and conc. of free HCl were measured. Vol. of gastric secretion was equal in both groups of rats (given electrical stimulation with or without previous dexamethasone treatment), but the pH of the gastric fluid in the untreated rats was clearly less than that of the dexamethasone group; the conc. of free HCl was much higher in the former than in the latter group, in which an almost complete degranulation of the mucosal mast cells was demonstrated histologically. The importance of the synthesis and accumulation of histamine in the mast cells of the gastric mucosa as a peripheral link in the stimulatory chain of gastric secretion is discussed.

11017 DIFFERENT HORMONAL RESPONSES OF MAST CELLS IN GASTRIC MUCOSA AND DERMIS IN THE RAT. (E.) Räsänen, T. (U. Helsinki). Scand. J. Gastroent. 2(2):118-123, 1967.

Four-mo.-old Wistar rats were divided into 6 groups according to treatment: Group 1, ACTH-zinc, admin. i.m. 4 x 2 I.U. at 24-hr. interval Group 2, ACTH as in the first group, plus asbestos 1.0 mg in sterile aqueous suspension o 1.0 ml as a single intra-abdominal inj. at the start of ACTH therapy; Group 3, asbestos as in the second group, 4 days before sacrifice; Grou 4, ACTH as in the first group plus heparin 9 x 1.0 mg at 12-hr. intervals; Group 5, hepari as in the fourth group; and Group 6, 6 x 0.5 ml of saline, admin. i.m. The responses of the gastric mucosal mast cells and the s.c. mast cells of the abdominal skin of the rat were studied after these procedures. The superficia portion of the gastric mucosa contained roughly 5 times as many mast cells as the s.c. connecti tissue. After ACTH, the mast cell count in the gastric mucosa decreased clearly after both heparinization and asbestos admin.; approx. 75% of the gastric mucosal mast cells were degranulated. Peritoneal irritation with steri asbestos alone produced a weak decrease in the count of mucosal mast cells. There was no clea increase in the mast cell count after hepariniz tion. The number of s.c. mast cells was fairly stable in the different phases of the experimen after admin. of ACTH, asbestos and heparin. Th observed differences indicate that mast cells in the gastric mucosa and in the epidermis may have important special, but clearly differing, functions. In the gastric mucosa, the sensitiv ness of the mast cells is possibly connected with their function as a peripheral mediator of stimulation of gastric secretion.

11018 THE EFFECTS OF VARYING THE EXTRACELLULAR POTASSIUM CONCENTRATION ON THE SECRETORY RATE AND ON RESTING AND SECRETORY POTENTIALS IN THE PERFUSED CAT SUBMANDIBULAR GLAND. (E.) Petersen, O. H. (U. Copenhagen) and J. H. Poulsen. Acta Physiol. Scand. 70(3-4 293-298, 1967.

In young cats, the left submandibular gland and its duct were prepared for perfusion; the perfusion fluid was a Locke's soln. of the following composition (mmoles/liter): Na, 142; K, 4.0; Ca, 1.5; Mg, 1.0; Cl, 127; HCO_3, 22; HPO_4, 1.1; and glucose, 10.0; modified Locke's soln. with the following K conc. were used: 0.2, 0.5 20.0 and 50.0 mmoles/liter; in these cases corresponding changes in the Na conc. ensured constant osmolarity. Secretory potentials were evoked partly by electrical stimulation (10 cycles/sec.; 10 volts) of the chordalingual nerve, and partly by inj. of acetylcholine (5 μg) into a common carotid artery cannula. For experiments with measurement of the secretory rate a continuous infusion of acetylcholine (70 μg/min.) was used. Potentials were never

corded until at least 5 min. (generally 10 min.)
d elapsed after changing the perfusion fluid.
e sensitivity of resting potentials and secre-
ry potentials to changes in K conc. was the
me; both increased to the greatest value at
5 mmoles/liter of K and decreased almost
nearly at 4 and 20 mmoles/liter of K. Both
creased when the K conc. was changed from 0.5
0.2 mmoles/liter of K. At extracellular K
nc. of 50 mmoles, a secretory potential of 5
llivolts could be evoked at a resting potential
-22 millivolts. Comparison of the secretory
tes at different K conc. (4 and 0.2; 4 and 0.5;
and 20), the secretory rates were always greater
the lowest conc. of K. Comparison of the
zes of the secretory potentials and the
cretory rates at different K conc. in the
rfusate showed that at 0.2 and 0.5 mmoles/liter
K, the secretory rate was greater than the
cretory potential, and increased linearly in
rallel from 0.2 to 0.5; the secretory rate
creased to the value of the secretory potential
4 mmoles/liter of K, and decreased to a value
ss than that of the secretory potential at 20
oles/liter of K. These findings support the
ndberg hypothesis that secretory potentials in
livary glands are due to an active transport of
ions, which transport should be responsible
the formation of the saliva. It is concluded
at the secretory potentials and the secretory
te depend in much the same way on the extra-
llular K conc.

019 THE EFFECT OF RATE OF GLAND FUNCTION ON PAROTID FLUID URIC ACID LEVELS.
.) Shannon, I. L. (USAF Sch. Aerospace Med.,
ooks Air Force Base, Tex.) and H. H. Chauncey.
. Air Force Sch. Aerospace Med. SAM-TR-67-29:
, 1967.

55 healthy, young adult male enlistees who had
sted overnight, single unstimulated and 5 pairs
exogenously stimulated parotid fluid samples
re collected at as near rest conditions as
ssible. Stimulation was effected by admin. of
ric acid in increasing conc. of 0.1%, 0.2%,
%, 0.8% and 1.6%; sample time for stimulated
llections was 10 min. during which acid portions
re taken at 1-min. intervals and held for 30
. Venous blood samples were collected after
last sample of parotid fluid was taken. Uric
d determination was achieved by the uricase
ocedure in the case of both serum and parotid
uid samples. The mean serum uric acid level
all subjects was 5.04 mg/100 ml. The admin.
increasing conc. of citric acid led to 5.6,
, 11.7, 14.9 and 19.7-fold increase in uric
d flow rates over the unstimulated rate. This
fference was highly significant. As the mean
w rate increased (0.046 to 0.908 ml/min.) the
n uric acid conc. decreased (10.03 to 3.09
100 ml). As the flow rate was increased, the
n uric acid secretion rate increased pro-
ssively to a high of 26.41 µg/min. This
fference between the mean unstimulated and
mulated uric acid secretion rate was also
significant. It is concluded from these data, that collection flow rates of parotid fluid for uric acid determinations should be 0.7 ml/min. or more.

11020 OBSERVATIONS ON THE SECRETION OF THE SUBMANDIBULAR AND SUBLINGUAL GLAND OF MOUSE EMBRYO UNDER NORMAL CONDITIONS AND IN CULTURE. (It.) DiGiovine Vecchione, L. (U. Naples, Italy). Histochemie 9(3):203-216, 1967.

Under normal conditions secretory activity of submandibular and sublingual glands of mouse embryo becomes histochemically detectable intracellular material at the sixteenth day of gestation. At the seventeenth day differences may be shown between the 2 glands in the morphological features of the secretion as well as in the intensity of the periodic acid-Schiff, Hale's and alcian blue histochemical reactions and in the behavior towards toluidine blue. The latter dye gave metachromatic staining after sulfation in the sublingual, but not in the submandibular gland, indicating that the polysaccharide component of the secretion has different characteristics in the 2 glands. With in vitro cultures (made on a clot of chicken plasma and embryo extract) of glands at the thirteenth day of gestation, secretion appeared at the same total age as with the in vivo glands but the ramification process went on at a slower rate. The glands developed in vitro for 10 days and their histochemical features appeared to be comparable to those which were observed in normal developmental conditions. At explantation time, they were just beginning their differentiation and both consisted of an epithelial cord and a solid bud and were contained in a common mesenchymal capsule.

11021 EFFECT OF EPINEPHRINE ON INSULIN RELEASE IN MAN INDUCED BY SECRETIN. (E.) Nelson, J. K. (Johns Hopkins Hosp., Baltimore, Md.), D. Rabinowitz and T. J. Merimee. Nature (London) 215(5103):883-884, 1967.

After an overnight fast, 4 normal female subjects were given an infusion of epinephrine (4-8 µg/min.); 45-min. later, an i.v. inj. of 75 U of secretin was given. During the initial period of epinephrine infusion, the conc. of plasma insulin did not change appreciably from those before infusion, despite significant elevations in the conc. of plasma glucose in all 4 subjects (av. rise 51.6 mg/100 ml; range 37.0-70.5 mg/100 ml). When secretin was admin., conc. of plasma insulin rose in all 4 subjects (av. rise 28.5 µU/ml; range 5-52 µU/ml). The greatest increases occurred at 2 min. and then rapidly fell to approach pre-inj. values within 10 min. When epinephrine infusion was discontinued, all subjects showed a marked rise in plasma insulin values that were greatest at 10-30 min. Two subjects were investigated with an identical dose of secretin when hyperglycemia was produced by infusion of 300 mg of dextrose/min.; conc. of plasma glucose rose to 47.9 and 46.5 mg/100 ml, and those of plasma insulin increased 19 and 9 μU/ml, resp., after 45 or 80 min., at which time they were given an identical dose of secretin as in the epinephrine experiment; plasma insulin conc. promptly rose, reaching a peak at 4 min., which represented a further rise of 25 and 26 μU/ml, and rapidly fell thereafter. It is concluded that secretin can, in the presence of hyperglycemia, cause a significant elevation in conc. of plasma insulin; this effect is not inhibited by epinephrine, an agent that blocks release of insulin observed after i.v. admin. of glucose. Secretin thus fulfils the requirements as a mediator of the mechanism which produces the augmented secretion of insulin observed after p.o., as compared with i.v., admin. of glucose.

11022 K$^+$-STIMULATED PHOSPHATASE OF MICROSOMES FROM GASTRIC MUCOSA.

(E.) Forte, J. G. (U. California, Berkeley), G. M. Forte and P. Saltman. J. Cell Physiol. 69(3):293-304, 1967.

The light microsomal fraction was isolated from homogenates of rabbit and bullfrog gastric mucosa. Upon examination with the electron microscope, the light microsomes appeared as tubular membranous structures with morphology and dimensions similar to the elements of the smooth-surfaced endoplasmic reticulum observed in intact oxyntic cells. A K-stimulated, Mg-requiring p-nitrophenylphosphatase was demonstrated in the gastric microsomes. Neither Na nor ouabain (10^{-6} to 10^{-3} M) altered the K-stimulated phosphatase. Thiocyanate was not very effective as an inhibitor of the gastric microsomal phosphatase, in contrast to the effect of this anion on the ATPase activity; however, the gastric phosphatase as well as the ATPase were destroyed by phospholipase C, thereby showing the lipoprotein nature of these enzymes. Kinetics of the K-ion activation of the microsomal phosphatase suggest that the K-ion-p-nitrophenylphosphatase complex is the active substrate for the enzymic reaction. Rb, NH_4 and Cs were found to substitute to some degree for K ion as an activator of the microsomal phosphatase. It is pointed out that K ion is an essential requirement for HCl secretion in intact gastric mucosa and the replacement of K ion with Rb, Cs and NH_4 is discussed. The K-ion stimulated phosphatase presented in this study may play a role in the H-ion secretion process.

11023 PROTECTIVE ACTION OF SALIVA IN PEPTIC ULCERATION. STUDIES ON THE EFFECT OF SALIVA ON GASTRIC SECRETION WITH DYE-DILUTION TECHNIQUE.

(E.) Malhotra, S. L. (Jagjivan Ram Hosp., Bombay, India). Scand. J. Gastroent. 2(2):95-104, 1967.

The effect of saliva on gastric secretion was studied in 41 adult men (17-53 yr. old, with a mean of 33 yr.) by the method of serial test meals. The essence of the experiments was to exclude saliva from the stomach in 1 set of observations and allow its admixture with food in the other set. The gastric acidity was significantly reduced by ingestion of saliva both in the case of fluid, as well as solid, meals. Differences in the mean acidities of the samples were larger in the case of masticatory meals, whereas in the case of nonmasticatory mash meals these differences were insignificant. Mucus in the aspirates from the stomach was mostly of salivary origin, and it appeared likely that the buffering action of saliva was exerted not only through its bicarbonate content, but also through its mucus content. Variations were observed in the titer of group-specific substances as well, but their significance was less clear. These findings have implications with regard to the possible protective action of saliva in peptic ulceration. If, as suggested previously, lack of ingestion of sufficient saliva, depending on the nature of the diet and the pattern of eating, is a major factor in development of peptic ulcer, there is hope that this disease may be controlled and prevented by preparation of diets in a manner that requires thorough mastication and ingestion of larger quantities of saliva of higher buffer capacity, greater mucus conc. and in larger total quantities.

11024 BLOCKADE OF VITAMIN B_{12}-BINDING SITES IN GASTRIC JUICE, SERUM AND SALIVA BY ANALOGUES AND DERIVATIVES OF VITAMIN B_{12} AND BY ANTIBODY TO INTRINSIC FACTOR.

(E.) Gottlieb, C. W. (Mount Sinai Hosp., New York City), F. P. Retief and V. Herbert. Biochim. Biophys. Acta 141(3):560-572, 1967.

A variety of vitamin B_{12} analogs and derivatives (pseudo-vitamin B_{12}, anilide-B_{12}, aquoanilide-B_1 cobinamide, cobrynamide, 5,6-dimethylbenzimidazo and 5 different cobaloxime compounds) were teste for their ability to reduce the unsaturated vitamin B_{12}-binding capacity of gastric juice, serum and saliva. The effect of these substance on specific binders in body fluids tested, was determined by rapid DEAE-cellulose chromatograph All vitamin B_{12}-like substances, except cobaloximes and 5,6-dimethylbenzimidazole, bound well to non-intrinsic factor vitamin B_{12} binders in normal gastric juice. Conversely only intrinsic factor antibody and cyanocobalamin blocked radioactive vitamin B_{12} binding to intrinsic factor. The B_{12} binders in pernicious anemia gastric juice were not effectively blocked by either intrinsic factor antibody or analogs. The precluded use of analogs instead of intrinsic factor antibody for assay *in vitro* of intrinsic factor in gastric juice in the system described. Unsaturated vitamin B_{12}-binding capacity of normal, chronic myelogenous leukemia and pernicious anemia serum was affected very similarly, and in a pattern resembling that of the nonintrinsic factor binder of normal gastric juice, except that cobaloxime C_3, was effective in reducing

: serum binding of vitamin B_{12}. Chromatography
owed equal reduction of both α-globulin and
lobulin binders. Analog interference with
amin B_{12} binders in saliva was essentially
nilar to, but more pronounced than, the results
:h serum and nonintrinsic factor binders in
tric juice.

)25 TOTAL NITROGEN CONTENT OF HUMAN
DUODENAL JUICE BEFORE AND AFTER
RAVENOUS INJECTION OF SECRETIN. (E.)
ersen, H. (Ulleval Hosp., Oslo), J. Myren and
P. Foss. Scand. J. Gastroent. 2(1):1-6,
7.

ability of secretin to alter total N content
duodenal juice was evaluated on 29 occasions
27 adult hospitalized patients; 2 patients
mined twice were recorded as 4 patients. The
ients were divided into a patient group with
mal pancreatic function (8 men, 8 women;
71 yr. old, with an av. of 49 yr.), in whom
clinical diagnosis was no organic disease in
duodenal ulcer in 3, diarrhea of unknown
gin and abdominal pain in 2 each, and 1 each
h drug-induced diarrhea, regional enteritis,
atic cirrhosis and pancreatic carcinoma; a
ient group with pathological pancreatic func-
n (5 men, 8 women; 16-73 yr. old, with an av.
53 yr.) included 6 with chronic pancreatitis,
ith diarrhea of unknown origin, 2 with liver
ease with unknown etiology, and 1 each with
creatic carcinoma and parasitic disease. The
n conc. of total N was approx. 100 mg/100 ml
duodenal juice before stimulation with secretin
dropped to approx. half this value after
retin; in patients with pathological values
vol. or bicarbonate conc. after secretin inj.,
decrease in total N conc. after stimulation
significantly less. The av. value of total
onc. and that evaluated from total protein
ermination were 100 mg and 10-20 mg/100 ml,
p.; this discrepancy was explained by a rapid
radation of proteins in the duodenal juice.
total N determination was inferior to estima-
n of bicarbonate conc. in differentiating
ween a normal and pathological pancreatic
ction, but similar to that of vol. rate and
erior to the estimation of amylase activity.
ore secretin stimulation a highly significant
relation was found between the conc. of total
nd those of total protein and amylase activity.
er stimulation a slighter, significant
relation only was found between the conc. of
al N and total protein in the first 20-min.
t-secretin period.

26 SOME PRACTICAL PROBLEMS RESULTING FROM
THE LEVEL OF PEPTIC ACTIVITY OF HUMAN
TRIC JUICE. (Fr.) Bonfils, S. (Bichat
p., Paris), J. Vatier, P. Zeitoun, M. Dubrasquet
Y. Lemercier. Rev. Franc. Etud. Clin. Biol.
4):349-358, 1967.

varying composition of gastric juice,
ecially protein and mucus content, and the

specific type of substrate were studied in 94 different gastric juice samples. The best substrate found for this experiment was 5% plasma. The amount of tyrosine (µg/ml) produced in 10 min. at 37°C was taken as an index of peptic activity; a preparation without substrate in each case was tested for endogenous tyrosine which was subtracted from the value obtained with substrate. The pH of the digest was adjusted to a value between 2.0 and 3.5 with N HCl. However, the free acidity was variable and the peptic activity changed in a very sporadic manner. With the factors which cause these variations eliminated, thus giving a sample of gastric juice that could be reproduced, a useful clinical method may evolve.

11027 POTASSIUM IN GASTRIC JUICE UNDER NON-STEADY-STATE CONDITIONS. (E.) Öbrink, K. J. (U. Uppsala, Sweden) and M. Waller. Scand. J. Gastroent. 2(1):44-48, 1967.

In a Heidenhain pouch dog, the K ion conc. of the gastric juice was analyzed after continuous i.v. inj. of histamine dihydrochloride (0.3 and 1.5 mg/hr.) following a starvation period of at least 12 hr.; when a steady-state condition was obtained, the inj. rate was suddenly changed to another higher or lower value, thus causing the secretion rate to increase or decrease to a new steady-state level. The steady states of the secretion rates and changing over from different steady states were studied. The conventional observation that the K conc. is independent of the secretion rate in the steady state was confirmed, but it was also found that during an increase of the secretion rate, the K conc. in the juice showed a transient increase. In changing the secretion rate to a lower steady level, the K conc. showed a similar deviation in the opposite direction before returning to its steady-state level. It is suggested that this phenomenon is due to a loss and uptake of K by the mucosa when stimulation is begun or terminated.

11028 LATENCY OF THE GASTRIC SECRETORY RESPONSE TO SHAM FEEDING IN THE DOG. (E.) Preshaw, R. M. (McGill U., Montreal, Canada). Canad. J. Physiol. Pharmacol. 45(4): 633-641, 1967.

Three conscious mongrel dogs were prepared with gastric fistulas. Sham feeding (with 600 g commercial dog ration) caused an increase in acid output after a mean delay of 6.4 min., and pepsin output was similarly increased after 5.9 min. The mean peak rate of secretion of acid in 25 min. after beginning sham feeding was 919 µEq/min., and was attained 13.4 min. after the stimulus was begun; for pepsin output the peak rate was 409 U/min., reached 11.6 min. after sham feeding was begun. Infusion of gastrin alone caused a graded increase in output of both acid and pepsin as the dose (0.313-80 g/hr.) was increased; the highest dose (80 g/hr., admin. i.v.) caused the highest rate of acid secretion (mean, 868 μEq/min.) and of pepsin output (mean, 252 U/min.). In other experiments, an infusion of 20 g gastrin i.v./hr. stimulated acid output after a mean delay of 9.5 ± 0.8 min. When a background secretion was induced with various doses of hog gastrin, the latency of the acid response to sham feeding was unchanged, but the latency of the pepsin response was shortened. The peak rates of acid and pepsin secretion after sham feeding were not altered by the infusion of gastrin. The observation that the latency of the pepsin response to sham feeding could be significantly reduced by a background gastrin stimulation indicated that the glandular cells responsible for pepsin secretion had a shorter latency than the acid-secreting cells.

11029 OXIDATIVE PHOSPHORYLATION AND THE EFFECTS OF SCN ON MITOCHONDRIA ISOLATED FROM RABBIT STOMACH. (E.) Forte, J. G. (U. California, Berkeley), G. M. Forte, R. Gee and P. Saltman. Biochem. Biophys. Res. Commun. 28(2): 215-221, 1967.

Mitochondria were isolated from rabbit gastric mucosa and incubated in a respiration medium containing 63 mM histidine-HCl buffer (pH 7.5), 4 mM $MgCl_2$, 85 mM sucrose, 2 mg/ml bovine serum albumin and 11 mM sodium glutamate as substrate. Respiration was polarographically measured at 24°C. Calculated ADP/O values for various gastric mitochondrial preparations were between 2.2 and 2.7; rabbit kidney cortex mitochondria prepared by similar procedures gave ADP/O ratios of 3.0 for the same substrate. The coupling ratios between fully supplemented mitochondria and those limited by ADP acceptor were lower in gastric (range 4.0-6.0) than in kidney (7.0-9.0) mitochondria. Addition of thiocyanate ion reduced the respiratory rate of fully supplemented mitochondria, but relatively high conc. were required; 40-50 mM thiocyanate ion produced 50% inhibition. Relatively high conc. of thiocyanate ion were required to reduce mitochondrial ATPase activity of intact rabbit stomach mitochondria. These results show that mitochondria isolated from rabbit gastric mucosa have mechanisms of oxidative phosphorylation and respiratory control typical of mitochondria from many tissues. That gastric mitochondria do readily synthesize ATP makes it unlikely that the H ions of the secretory product are provided by substrate H atoms directly linked to electron transfer, through the mitochondrial cytochrome chain, to molecular O_2. The results also demonstrate that thiocyanate ion does inhibit mitochondrial function, i.e., oxidative phosphorylation, respiration and ATPase; however, the conc. of thiocyanate ion required to produce significant decrements in these parameters is considerably higher than that required to inhibit H ion secretion by gastric mucosa. It is thus unlikely that thiocyanate ion manifests its primary effect on H ion secretion by inhibiting mitochondrial reactions.

11030 NATURE OF THE GASTRIC SECRETAGOGUE IN ZOLLINGER-ELLISON TUMOURS. (E.) Gregory, R. A. (U. Liverpool, England), M. I. Grossman, H. J. Tracy and P. H. Bentley. Lancet 2(7515):543-544, 1967.

Two pancreatic tumors, 1 weighing 2.5 g and the other 17 g, were obtained from cases of the Zollinger-Ellison syndrome. Extracts were prepared separately by the first stage of the metho of Gregory and Tracy for isolation of gastrin from antral mucosa, and aliquots of the extracts were shown to stimulate gastric acid secretion when inj. into conscious dogs. The remainders c the 2 extracts were then combined and taken through the remaining stages of the procedure for isolation of gastrin, ending with a single stage of chromatographic fractionation on amino-ethylcellulose. Amino acid analyses of the remaining extract and of human gastrin, as well as other chemical characteristics of the extract indicates that Zollinger-Ellsion tumor contains 1 or the other, or both, of the gastrin peptides which have been isolated from human antral mucos

11031 GASTRIN-LIKE EFFECTS OF CHOLECYSTOKIN PANCREOZYMIN. (E.) Celestin, L. R. (Southmead Hosp., Bristol, England). Nature (London) 215(5102):763-764, 1967.

The effects of pure cholecystokinin-pancreozymin (admin. i.v. at a constant rate of 2 Crick, Harper and Raper U/kg/hr.) on the human stomach and pancreas were compared with the response of these same organs to a gastrin analog (a tetrapeptide, admin. i.v. at a rate of 0.5 μg/kg/hr.) at these conc. responses were submax. Cholecystokinin-pancreozymin induced an acid response in the resting stomach, increasing both the vol. and conc. of the acid and leading to a steady level of secretion (av. 12 mEq/hr.) in approx. an hr.; a very similar response was obtained with the gastrin analog (av. 14 mEq/hr.). In both cases, a rise in the H ion conc. was accompanied by a fall in Na ion conc. When both substances were given together at these rates, the one on a background infusion of the other, whether the analog preceded or followed the cholecystokinin-pancreozymin, the acid response of the stomach exhibited an additive effect, with no evidence of potentiation (av. 16.5 mEq/hr.). When tested on the pancreas, both substances induced a similar pattern of output of amylase and trypsin. It is concluded that cholecystokinin-pancreozymin displays gastrin-like effects; it is possible that cholecystokini pancreozymin and not gastrin, accounts for the gastrin-like activity found in extracts of duodenal mucosa. The similarity of action of these 2 hormones suggests that they may have important amino-acid sequences in common.

11032 INHIBITION OF GASTRIC ACID SECRETION BY INTRAVENOUS CHOLECYSTOKININ EXTRACT (E.) Bedi, B. S. (Western Infirm, Glasgow,

tland), J. P. Govaerts, S. P. Master and I. E.
lespie. Scand. J. Gastroent. 2(1):68-76, 1967.

rapid single i.v. inj. of the cholecystokinin
paration Cecekin (75 clinical U) inhibit the
ponses of Heidenhain pouch dogs to stimulation
gastrin extract or synthetic gastrin-like penta-
tide (20 μg/hr., admin. i.v.) at both submax.
supramax. dose rates, to histamine (dihydro-
oride, 0.125-0.5 mg/hr., admin. i.v.) to the
ole cholinergic drug methacholine (1 mg/hr.,
in. i.v.) and to feeding a meat meal (11 ounces).
pattern of inhibition suggested that the
ibitor effect was exerted in the region of the
d-secreting cell. Pure cholecystokinin
ibited the acid response of the Heidenhain
ch dogs to histamine. Although both pure
retin and pure cholecystokinin are possible
ibitor agents arising from the duodenal mucosa,
is likely that endogenous duodenal acidifica-
n releases a further, as yet unidentified,
oral inhibitor agent, or that secretin and/or
lecystokinin may act in collaboration with
n other or a further inhibitor agent. In
nals with both a Heidenhain pouch and a simple
cula into the normally vagally-innervated
tric remnant and in which antrectomy had been
formed, a single rapid i.v. inj. of the
ecystokinin preparation had no effect on the
lenhain pouch responses to the continuous i.v.
sion of histamine. However, the acid output
n the main gastric remnant was increased by
cholecystokinin inj. The possibility is
ed that this cholecystokinin preparation
ains some gastrin-like activity.

3 PENTAPEPTIDE INFUSION TEST. (E.)
Konturek, S. J. (1st Intern. Dis.
., Cracow, Poland) and J. Lankosz. Scand. J.
roent. 2(2):112-117, 1967.

apeptide was admin. by continuous i.v.
sion to 20 subjects (10 healthy males, 10
enal ulcer patients) at a dose of 1.5 μg/kg/hr.,
histamine was similarly given at a dose of
g/kg/hr. The pentapeptide was also given
healthy volunteers either i.v. in graded
s of 0.3-1.5 μg/kg/hr. or s.c. at 7.5 μg/kg,
also histamine, either i.v. in doses of
0 μg/kg/hr. s.c. at 40 μg/kg. Pentapeptide
sed i.v. in graded doses provoked at a dose
.5 μg/kg/hr. a peak acid output which was
ificantly higher than the acid secretion
ced by i.v. histamine in a dose of 40 μg/kg/hr.
he 5 healthy subjects. The pentapeptide
sion test at a dose of 1.5 μg/kg/hr.
ared to be a very reproducible and safe mode
astric stimulation giving a sustained and
level of gastric secretion in the 20 test
ects. When the stimulants were inj. in
le s.c. doses the mean acid output induced
entapeptide in a dose of 7.5 μg/kg was higher
the acid response to histamine in a dose of
g/kg, but this difference was not statisti-
y significant. Peptic ulcer patients showed
gher response to both kinds of stimulant, but the shape of the acid response curve was almost the same as in healthy subjects. The acid response to pentapeptide increased more abruptly and reached a higher level than when histamine was used. The infusion test with pentapeptide had some advantage over histamine stimulation in so far as it was safe and almost completely free of side-effects. It is concluded that the pentagastrin infusion test in a dose of 1.5 μg/kg/hr. is the best mode of stimulation available and can produce the highest rate of gastric secretion in man.

11034 THE INFLUENCE OF GASTRIN ANALOGUES ON GASTRIC, PANCREATIC AND BILE SECRETION. (E.) Konturek, S. (1st Intern. Med. Clin., Cracow, Poland). Acta Med. Pol. 8(2):201-212, 1967.

In cats, the max. gastric acid production (approx. 640 μEq/15 min.) induced by histamine was from a s.c. dosage of 40 μg/kg and this peak was similar to the response to a gastrin tetrapeptide, at a s.c. dose of 20 μg/kg and slightly smaller than the max. acid secretion evoked by gastrin pentapeptide at a s.c. dose of 40 μg/kg. Acid secretion remained unchanged with further increase in dosage but animals exhibited signs of intolerance with supramaximal doses of histamine, but not with the peptides. The shapes of response curves with histamine in cats with gastric fistulas differed slightly from those with the gastrin analogs; with the latter, a sudden increase in acid output was seen almost immediately which peaked in the second 15-min. period, whereas with histamine, the increase started at the end of the first period and peaked in the third or fourth 15-min. period. Both peptides in large rapid i.v. doses failed to produce an inhibitory effect on acid secretion, but always augmented it. Vagotomy reduced the activity of parietal cells to these gastrin-related peptides about twice as much as to histamine. These peptides also increased pancreatic secretion (peaked at 20% above max. secretion), bile flow, and bicarbonate output.

11035 EFFECT OF INSULIN AND 2-DEOXY-D-GLUCOSE ON HCL SECRETION FROM THE NORMAL AND VAGALLY DENERVATED STOMACH. (E.) Konturek, S. (1st Intern. Med. Clin., Cracow, Poland). Acta Med. Pol. 8(2):195-200, 1967.

When dogs with gastric fistulas and vagally-denervated pouches of the fundic gland area were inj. i.v. with 100-200 mg/kg of 2-deoxy-D-glucose or with 0.5-1.5 μg/kg of insulin during basal gastric secretion, an increase proportional to the dose in acid output was recorded from the vagally-innervated stomach which lasted about 2-3 hr. for 2-deoxy-D-glucose and 3-4 hr. for insulin. At the same time, the Heidenhain pouch did not show secretory activity. However, these products produced different responses when the dogs received constant i.v. infusions of histamine at the rate of 5 mg/hr. With 2-deoxy-D-glucose, the histamine induced acid response from the innervated stomach increased about twice as much as when 2-deoxy-D-glucose or histamine alone were used. This increase in gastric secretion lasted more than 6 hr. In contrast, with insulin the histamine-induced gastric secretion was as follows: a slight and transient increase in acid output from the gastric fistula which was followed by a significant reduction in secretion (about 60% of the control) and a decrease to 65% of the control in acid output from the Heidenhain pouch. It is concluded that 2-deoxy-D-glucose would be a more effective tool than glucose for examining gastric vagal innervation and vagal integrity.

11036 EFFECT OF INFUSION OF HISTAMINE IN NORMAL SALINE AND IN GLUCOSE ON GASTRIC SECRETION IN RATS WITH PERMANENT GASTRIC FISTULAS.

(E.) Kowalewski, K. (U. Alberta, Edmonton, Canada). Arch. Int. Physiol. 75(3):450-454, 1967.

Chronic gastric fistula permits the study of both basal and stimulated gastric secretion in small experimental animals, and is practical in the study of gastric function in rats in which a stimulant was infused i.v. for a prolonged period of time. Infusion of histamine in normal saline for 24 hr. in Sprague-Dawley male rats with chronic gastric fistula resulted in an adequate stimulation of gastric secretion. When histamine was infused in 5% glucose no such stimulation was seen. Control animals were infused with saline and glucose. No significant difference was found between gastric secretions of the rats perfused with normal saline and 5% glucose.

11037 ACID SECRETION OF THE STOMACH AFTER MAXIMAL HISTAMINE DOSAGE. (Ger.)

Kaess, H. (Med. U. Clin., Heidelberg, Germany) and E. Oeckinghaus. Klin. Wschr. 45(16):809-814, 1967.

Gastric secretion was measured in four 15-min. intervals during the hr. after admin. of 0.03 mg/kg of histamine dihydrochloride to 207 subjects, (95 males, 112 females) 49 with normal gastrointestinal tracts, 37 with mild superficial gastritis, 49 with severe superficial gastritis, 43 having gastritis with atrophy, and 29 with atrophic gastritis. Biopsy of gastric mucosa was made in each case with a decrease of acid secretion corresponding to increased mucosal atrophy. Except in cases of atrophic gastritis, acid secretion in females was about 70% of that found in male patients. A significant influence of age and wt. on the secretion of gastric acid was found only in males with light superficial gastritis and chronic gastritis with atrophy. The normal range for males with normal mucosa of the gastric body was 10.2 mEq HCl/30 min. and 17.4 mEq HCl/hr.; for females the corresponding values were 7.0 and 12.1 mEq HCl. The wide variation of acid secretion in different histologically-defined conditions limits the value of the augmented histamine test.

11038 RADIOLOGICAL DETERMINATION OF THE ACI LEVEL IN GASTRIC CONTENTS. (Pol.)

Szczepański, J. (Municipal Hosp., Biala Podlaska Poland). Pol. Tyg. Lek. 22(11):383-386, 1967.

A new tubeless method for the determination of free HCl in the stomach is described. It consists of p.o. admin. of a 0.3 g $BaSO_4$ tablet coated with an acid-sensitive agent (prepared from dimethyl-amino-ethyl ester of polymethacry acid) and estimating, by fluoroscopy, the necessary time for disintegration of the coatin in the stomach. The time of reaction between the coating and the free HCl depends on its con in the stomach. The coating is pharmacological inert, nontoxic and does not affect gastric juice or its enzymes. Fluoroscopic examination were started 8-10 min. after swallowing the tablet (whole) and subjects were checked at 2-3 min. intervals; a 3-4 sec. observation of the condition of the tablet was sufficient and the test ended when the time required for complete dissolution of the coating was recorded. The exposure to X-rays using typical values (ki volt and milliampere) and the appropriate filte is insignificant (less than 10% of a chest X-ra This method was tried on approx. 1000 subjects (585 with digestive tract symptoms) and comparisons with values obtained by the usual gastric probe method and titration on 163 subjects showed agreement in 96.94% of cases. The max. differences were 6, 7, 11, 15 and 34 titered acid U corresponding to 0.02%, 0.03%, 0.05% and 0.13% of free HCl, resp. This was attributed t technical mistakes in coating of the tablet.

11039 ADRENALIN EXCITOSECRETORY ACTION IN THE CAT. (Fr.)

Laboury, S. (U. Lieg Belgium). C.R. Soc. Biol. (Paris) 161(2): 485-487, 1967.

Continuous pH recordings were made of gastric acidity as gastric juice was aspirated in 19 cats; epinephrine HCl (200 µg/kg) diluted in saline was infused through the jugular vein; atropine sulfate was inj. i.p., then i.v. 30 min. before, as well as immediately after, the inj. of epinephrine; each time dosage was 1 mg/kg. Cervical bilateral vagotomy was done. The epinephrine produced an immediate drop to pH 3 in 7 of 11 animals; this acid secretion ceased when the epinephrine infusion was interrupted and reappeared after a short latent period when infusion was resumed. The same aci hypersecretion was observed in 2 of 5 cats following separate i.p. inj. of 200 µg/kg of epinephrine. Atropine (1 mg/kg) did not dimini the hyperacidity in all cases but section of th vagus nerves quickly decreased or completely prevented hyperacidity. The admin. of epineph (0.4 mg/kg, total) exceeded the gastric acid secretory action of histamine (100 µg/kg) admi either i.v. or s.c.

11040 RENNIN AND THE GASTRIC SECRETION OF NORMAL INFANTS.

(E.) Malpress, F.

Queen's U., Belfast, N. Ireland). Nature
.ondon) 215(5103):855-857, 1967.

ne secretion of rennin was studied in the
tomachs of young (premature and fullterm; age
ange, birth-6 wk. old) infants, using human
asein as substrate for pepsin and rennin. Sam-
les of gastric juice were aspirated from the
tomachs of both fasting and fed infants.
ctivity was measured by the increase in turbidity
aused by either pepsin or rennin acting on the
ubstrate at pH 5.65; a differential analysis
as based on the different rates of destruction
f the 2 enzymes in mildly alkaline soln. (pH 9)
: room temperature. A total of 22 samples was
xamined: 16 by the method of treatment with
kali (7 from fullterm and 9 from premature
nfants; age range at sampling, 0-31 days); 6 by
urbidimetry at pH 7.2 (1 fullterm and 5 from
remature infants; age range at sampling, 0-43
ays). No rennin activity was detected in any
ample. Nonrennetic activity expressed in terms
f pure pepsin, and uncorrected for dilution by
ilk in the case of fed infants, ranged from none
samples) to approx. 0.005%. The mean value
or 33 samples of gastric juice from human adults
ecently examined by Texter et al. was 0.084%.

041 INHIBITION OF GASTRIC ACID SECRETION
BY BACTERIAL LIPOPOLYSACCHARIDE. (E.)
llie, J. H. (Roy. Coll. Surg. England, London),
M. Limbosch and L. M. Nyhus. Nature (London)
5(5103):879, 1967.

ogs were prepared with vagally denervated pouches
the body of the stomach, and afterward gas-
ric secretion was stimulated by a low dose of
stamine (100 µg/hr.) admin. by constant i.v.
fusion. Gastric acid secretion was abolished
doses of 10 µg/kg of Pseudomonas polysaccharide
rogen admin. i.v. during stimulation with
stamine. Secretion failed progressively over
3 hr. during which time the dogs developed
rexia as indicated by a thermistor lodged in
e rectum. The potent action of lipopoly-
ccharide against secretion stimulated by hist-
nine is likely to reflect an effect on the
cretory mechanism and not on intrinsic or
trinsic nerves; alterations in gastric blood
ow could also be responsible for this effect.
e slow development of inhibition of secretion
these experiments, which seemed to run parallel
th rise in body temperature, suggests that
hibition of secretion, like pyrexia, depends
development of a mediator such as WBC
cterial pyrogen.

042 THE ANTIDIURETIC HORMONE AS AN INHIBITOR
OF GASTRIC SECRETION. (E.) Karlmark,
(U. Uppsala, Sweden) and K. J. Öbrink. Scand.
Gastroent. 2(2):124-128, 1967.

le Heidenhain pouch dogs were employed to study
e antidiuretic hormone as a physiological
hibitor of gastric acid secretion. Constant gastric secretion was stimulated with food; a continuous i.v. infusion of saline at the rate of 0.16 ml/min. was maintained throughout the experiment. When a constant gastric secretion rate had been achieved, pure saline was changed for a saline and antidiuretic hormone mixture (of different conc.) which was infused at the same constant infusion rate of 0.16 ml/min. The inhibition was expressed as a percentage and plotted against the dose of antidiuretic hormone. Lysine- and arginine-antidiuretic hormone were employed; the ED_{50} for both forms of antidiuretic hormone was 60-150 µU/kg; no difference in inhibitory power was found between these 2 forms. During inhibition of gastric acid secretion with antidiuretic hormone, H ion conc. decreased, Na ion conc. increased, Cl ion remained constant in conc. and K ion showed a transient dip during inhibition in every experiment. At 26 µU/kg min. there was evident inhibition of gastric secretion, and at 100 µU/kg min. there was 50% inhibition. A dose of 30 µU/kg min. markedly influenced the gastric secretion, which indicated that this inhibition may well occur under physiological conditions.

11043 INHIBITION BY GASTRONE OF RAT GASTRIC ACID SECRETION MAXIMALLY STIMULATED BY 2-DEOXY-D-GLUCOSE. (E.) Baume, P. E. (Roy. North Shore Hosp., Sydney, Australia) and A. Nicholls. Aust. J. Exp. Biol. Med. Sci. 45(Pt. 3):327-329, 1967.

After a 48-hr. fast, 4 groups of 10 female Sprague-Dawley rats each were subjected to ligation of the pylorus. Group 1 received a control inj. of 2 M urea solvent i.v. in a dose of 2.5 ml/kg. Group 2 received canine antral gastric mucus (gastrone) in a dose of 5 mg/kg contained in 2.5 ml/kg of urea solvent; this dose depresses rat gastric acid secretion 70% from control values. Groups 3 and 4 received the same treatment, resp., as Groups 1 and 2, but received in addition a s.c. inj. of 2-deoxy-D-glucose (600 mg/kg) at the time of pylorus ligation. Acid secretion by the 4 groups was compared. Acid output (mEq/100 g/4 hr.) in each of the groups was as follows: 1) 0.296 ± 0.058; 2) 0.062 ± 0.013; 3) 0.351 ± 0.044; and 4) 0.151 ± 0.018. These results show that the gastrone used was potent and that it could exert its depressant effect in the face of simultaneous stimulation of acid secretion by max. doses of a vagal stimulant; this suggests that gastrone exerts its action on acid secretion at a site in the gastric secretory process distal to the vagus nerves. These results also show that the inhibitory capacity of gastrone is slightly less if 2-deoxy-D-glucose is admin. simultaneously, suggesting that the vagal component acting directly on the secretory mucosa is still operative and that only the antral component of vagally-stimulated secretion is inhibited.

11044 EFFECTS OF CORTISONE ON PARIETAL CELLS AND ACID SECRETION IN DOGS. (E.)

Goksen, Y. (U. Mississippi Med. Ctr., Jackson) and J. D. Hardy. J. Surg. Res. 7(9):406-412, 1967.

The effects of 200 mg of cortisone daily for 3 wk. upon parietal cell mass and gastric secretion were measured in 6 dogs with Heidenhain pouches, 3 with Pavlov pouches and 3 with Heidenhain pouches and antrectomy. The 24-hr. secretory vol., free HCl and total acid were all significantly increased during cortisone treatment in dogs with both innervated and denervated pouches. The antrectomized animals showed a small but statistically insignificant increment in acid secretion on cortisone treatment. The max. secretory response to histamine showed a 2-fold increase during cortisone admin. in the 4 dogs studied. Mean parietal cell population was significantly decreased, 13% in dogs with Heidenhain pouches and 17% in dogs with Pavlov pouches. Since an increased secretion of histamine is usually associated with an increase in parietal cell mass, the rise in gastric acid secretion was attributed to an increased parietal cell sensitivity to normal stimuli in cortisone-treated animals.

11045 EXPERIMENTAL STUDIES ON ACID PRODUCTION OF THE STOMACH STIMULATED BY A SOLUTION OF SOLANINE. (Ger.) Hohnloser, E. (City Hosp., Pforzheim, Germany). Arzneimittelforschung 17(6):738-740, 1967.

Stimulation of gastric-acid production by 0.01% soln. of solanine, a sapanin, was compared to that of a standard alcoholic test-drink. The subjects were divided into 3 groups and only those with completed tests were used in compiling the results: Group 1, 49 subjects each received 250 ml of H_2O containing 50 drops of solanine; Group 2, 27 subjects first underwent the standard alcohol test for acid stimulation and then the solanine test with 50 drops of the sol., and Group 3, 19 control persons were each given 250 ml of water only to test the effect of mechanical stimulation. Collection of gastric juice was done in consecutive 10-min. samples; these were analyzed for total and free acid. Individual variations were observed in both tests. Stimulation was not diminished when solanine was admin. immediately following alcoholic stimulation. Solanine stimulation of total acidity was 43 U, as compared to alcohol (40), and of free acid was 32 as compared to 29 for the alcohol test. The duration of stimulation with solanine seemed to be longer than with alcohol. No side reactions were observed.

11046 DEGRADED AND UNDEGRADED CARRAGEENANS AND ANTIPEPTIC ACTIVITY. (E.) Anderson, W. (U. Strathclyde, Glasgow, Scotland) and J. E. Harthill. J. Pharm. Pharmacol. 19(7):460-467, 1967.

The antipeptic activities of a series of undegraded κ- and λ-carrageenans and degraded carrageenans were examined by 2 biochemical methods (modifications, resp., of Anson, and of Hunt); the activities were found to differ quantitatively. Compared with the κ-carrageenar the λ-carrageenans, as a group, had greater activity and this was associated with low 3,6-anhydro-D-galactose and high ester sulfate content. Within the series of undegraded carrageenans, both κ and λ, differences in antipeptic activity were significantly and positively related to differences in sulfate content. In addition to the effect of sulfate, 3,6-anhydrogalactose content appeared to be inversely related to activity but in the λ-serie only; differences in viscosity were without effect. Initial degradation without loss of sulfate resulted in loss of activity but furthe degradation, also without loss of sulfate, did not reduce activity further. Antipeptic activit appeared to depend on a combination of structura features, of which the differences between κ-λ carrageenans, molecular size and polyanionic properties were aspects.

11047 MEASUREMENT OF GASTRIC HYDROCHLORIC ACID AFTER MAXIMAL HISTAMINE STIMULATION WITH SPECIAL REFERENCE TO ACHLORHYDRIA. (E.) Christiansen, P. M. (Bispebjerg Hosp., Copenhagen). Scand. J. Gastroent. 2(2):105-111, 1967.

Titration to various pH end points was performe in all samples of gastric juice from 208 patien with gastrointestinal diseases and healthy persons, examined with the augmented histamine test. Excluding 27 contaminated with bile and 24 contaminated with food, samples were obtaine from 17 healthy subjects, 22 with prepyloric ulcer, 51 with duodenal ulcer, 26 with gastric ulcer, 13 with gastric cancer, 10 with gastriti 14 with gallbladder disease and 31 with miscellaneous gastrointestinal conditions. Titrat to pH 3.3 and to pH 7.0 revealed differences in H ion conc. which were significantly negatively correlated to the max. acid output, calculated from the acidity at pH 3.3. Differences betwee max. acid outputs, calculated from the aciditie at pH 3.3 and pH 7.0, varied only little in all examined groups, with the exception of gastric juice contaminated with food. Titration to pH or higher was found to be overestimated gastric HCl, especially in gastric juice from patients gastritis and gastric juice contaminated with f These results support previous investigations w recommend titration of gastric juice to pH 3.5 with simultaneous measurement of pH. Achlorhyd corresponding to absence of parietal cells is th defined by a pH higher than 3.5 and a pH fall l than 1 pH U from basal to max.-stimulated value

11048 COMPARISON OF METHODS OF EXPRESSING T RESULTS OF AUGMENTED HISTAMINE TESTS. (E.) Abernethy, R. J. (Western Infirm., Glasgow, Scotland), R. M. Ross, A. G. Cox, A. W. Ka and I. E. Gillespie. Brit. Med. J. 3(5559): 205-206, 1967.

consecutive series of 100 patients with duodenal
cer were studied before and after vagotomy with
simple drainage procedure. Each patient had
augmented histamine test and a medical vago-
my test before operation, and an augmented
stamine test and an insulin test approx. 8-10
ys after operation. The results of all aug-
nted histamine tests were expressed in 3
fferent ways: 1) "mid-half hr.", acid output
the 15- to 45 min. period after histamine; 2)
eak half-hr.", acid output in the 30-min.
riod giving the greatest response after hist-
ine; 3) "whole hr.", acid output in the 60 min.
ter histamine. Each of these methods of report-
g the results was compared with each of the
ners by calculating the correlation coefficient
tween each possible pair. There was an
ceptionally high degree of correlation between
ch pair of measurements in 1) the preoperative
gmented histamine response; 2) the medical
gotomy modification; and 3) the postoperative
gmented histamine response. Similarly, there
s good correlation between the 3 pairs of
asurements when the effects of medical and
rgical vagotomy were expressed as percentage
ductions of the preoperative augmented histamine
sponse. When differences between the results
subgroups of patients within the series were
alyzed, the differences were of the same
gnitude, regardless of the way in which the
sults were expressed. It is concluded that
riations in the method of expressing the re-
lts of the augmented histamine test are unlikely
alter the conclusions derived from a particular
ries of such tests. Therefore, it is likely
at conclusions in studies using different ways
expressing the test responses can be directly
ated with each another.

049 ACTIONS OF HEXOPYRRONIUM BROMIDE ON
GASTRIC SECRETION IN DOGS AND ON GAS-
C SECRETION AND ULCERATION IN RATS. (E.)
hin, R. S. (A. H. Robins Res. Labs., Richmond,
) and J. W. Ward. Arch. Int. Pharmacodyn.
(1):82-100, 1967.

eries of N-substituted-3-pyrrolidyl α-sub-
tuted phenylacetates were tested for their
ects on gastric secretion in rats. One mem-
of this series, hexopyrronium (1-methyl-3-
rolidyl α-phenylcyclohexaneglycolate metho-
mide) was further studied for its effects on
d, histamine and insulin-stimulated gastric
retion. Thomas-type innervated and Heidenhain-
e denervated gastric pouch dogs were used.
effect of this compound on ulceration in the
oric-ligated rat was also assessed. Hexo-
ronium proved to be an effective inhibitor of
tric secretion stimulated by food, insulin
histamine. The gastric secretory effects of
s compound on meal-stimulated secretion did
differ significantly from the results ob-
ned with atropine sulfate. The incidence of
e-effects (dry mouth, mydriasis) was greater
h the admin. of atropine. Hexopyrronium was
o effective in preventing the ulceration
duced by pyloric-ligation in fasted rats.

11050 SECRETION OF ACETYLCHOLINE BY GASTRIC MUCOSA AND ITS QUANTITATIVE CHANGES UNDER THE ACTION OF GANGLERON AND QUATERON. (Arm., Russ. Summ.) Virabian, I. L. Zh. Eksp. Klin. Med. 7(1):13-24, 1967.

The study was made on 3 dogs with Pavlov's pouch constructed from the lesser and greater curvatures. Acetylcholine extracted by trichloracetic acid was subsequently tested on the rectus abdominis muscle of the frog. Under the action of small doses of quateron [thriethyl (3-hydroxy-2-methylbutyl)-iodide, p-butoxybenzoate ammonium], the most significant increase in acetylcholine concn. was noted in the gastric juice (collected for 3 hr.) from the lesser curvature. The shifts in pepsin activity and free acid were less pronounced. Acetylcholine content under the influence of quateron (0.05 mg/kg) on stimulation with bread increased by 115.7% and with meat by 65%; pepsin increased by 39.8 and 47.6%, resp.; acid increased by 31.4 and 23.5%, resp.; gastric juice vol. increased by 37.1 and 29.3%, resp. In the secretion from the greater curvature on stimulation with bread, acetylcholine content increased by 42.3%, pepsin activity by 23.1%, acidity by 8.1%; and vol. by 8.1%; the resp. values on stimulation with meat were 28.5%, 11.0%, 12.6%, and 4.1%. Quateron in larger doses intensely inhibited acetylcholine content in the juice obtained from the lesser curvature; other indices showed less-pronounced shifts. Acetylcholine content on stimulation with bread and meat decreased by 61 and 60%, resp.; pepsin activity was inhibited by 56 and 64%, resp.; acidity by 46 and 45.9%, vol. by 50.8 and 50.3%, resp. In the juice from the greater curvature the resp. values were 42 and 65%, 47 and 65%, 40.7 and 49.9%, 45.9 and 50.3%. Gangleron (3-diethylamino-1, 2-dimethylpropyl p-isobutoxybenzoate) in larger doses markedly reduced the content of acetylcholine and other indices of gastric juice. Therefore, ganglion blocking agents have a pronounced effect on the acetylcholine content in the gastric juice. Apparently the changes occurring in acetylcholine metabolism are important in the mechanism of the therapeutic effects of quateron and gangleron.

11051 THE EFFECT OF PIPENZOLATE ON GASTRIC SECRETION IN MAN. (E.) Vincent, P. C. (Roy. North Shore Hosp., Sydney, Australia), B. H. Fenton and D. Beeston. Med. J. Aust. 1(11):546-548, 1967.

The following drugs were admin. p.o. to 2 patients undergoing insulin coma therapy 3 hr. before gastric secretion was measured: propantheline, 15 and 30 mg; oxyphencyclimine, 10 mg; and pipenzolate, 10 and 20 mg. The recommended doses (10 mg p.o.) of pipenzolate had no effect on saliva flow or hypoglycemic-stimulated gastric secretion, although larger doses had a slight effect. In the same subjects, both 30 mg of propantheline and 10 mg of oxyphencyclimine significantly inhibited gastric secretion. These results cast doubt on the therapeutic value of this preparation, in the doses recommended, in the treatment of peptic ulceration.

11052 RADIOAUTOGRAPHIC LOCALIZATION OF THE INCREASED SYNTHESIS OF PHOSPHATIDYLINOSITOL IN RESPONSE TO PANCREOZYMIN OR ACETYLCHOLINE IN GUINEA PIG PANCREAS SLICES. (E.) Hokin, L. E. (U. Wisconsin, Madison) and D. Huebner. J. Cell Biol. 33(3):521-530, 1967.

A technic in which the incorporation of tritium from myo-inositol-2-3H into phosphatidylinositol is followed by radioautography is studied. This permits the measurement of the incorporation of myo-inositol-2-3H into the lipid in various regions of the guinea pig pancreatic acinar cell. Stimulation of enzyme secretion with either pancreozymin or acetylcholine was associated with increased graining in both the basophilic and nonbasophilic cytoplasm. Most of the increase in graining due to stimulation with pancreozymin or acetylcholine plus physostigmine was abolished if the tissue was extracted with 2:1 chloroform-methanol before radioautography. On chromatography of lipid extracts of pancreas, the only lipid showing a detectable increase in radiography on stimulation with pancreozymin was phosphatidylinositol. The increase in graining is likely to be due to increased incorporation of tritium into phosphatidylinositol. There seems to be an increased synthesis of phosphatidylinositol in the rough-surfaced endoplasmic reticulum and in the smooth-surfaced Golgi membranes as a result of stimulation of enzyme secretion. The significance of these findings is discussed in relation to membrane circulation presumed to occur in the pancreatic acinar cells on stimulation of protein secretion. The increased synthesis of phosphatidylinositol may be concerned with the formation of new endoplasmic reticulum and with the Golgi membrane to replace that which is assumed to be converted to membrane of the zymogen granules during intracellular protein transport.

11053 THE PRESENCE OF BETA-RECEPTORS IN THE SUBMAXILLARY GLAND OF THE DOG. (E.) Emmelin, N. (U. Lund, Sweden) and J. Holmberg. Brit. J. Pharmacol. 30(2):371-378, 1967.

In dogs under chloralose-urethane anesthesia, secretion from the submaxillary gland evoked by stimulation of the vagosympathetic trunk was not affected by dihydroergotamine, but the vasoconstrictor response in the gland was abolished. Isoprenaline, admin. i.v., evoked a lively secretion from the gland, similar to that produced by sympathetic stimulation; the threshold dose was 0.5-2.0 μg/kg, and after 5-10 μg/kg a flow approx. as rapid as that caused by sympathetic stimulation at 20 shocks/sec. was produced. With epinephrine, a flow could be produced by inj. 5-10 μg/kg. These agents caused no flow of saliva from the parotid or sublingual glands. The secretory effects of a moderate dose of isoprenaline and epinephrine could be completel abolished by propranolol (0.5 mg/kg) or N-isopropyl-p-nitrophenylethanolamine (5 mg/kg). The secretion induced by vagosympathetic stimulation was more resistant, but it could be abolished when the doses of the blocking agents were raised 2-5-fold. It is concluded that the catecholamine-receptors of the submaxillary gla cells in the dog belong exclusively to the β-type. In this respect, this gland differs from all other salivary glands so-far investigated.

11054 THE EFFECT OF STIMULATION OF THE GYRU ZONE AND AMYGDALOID NUCLEI ON THE SECRETORY ACTION OF SALIVARY AND GASTRIC GLANDS (Ukr.) Bogach, P. G. (U. Kiev, USSR) and Nguye Ting Tsao. Fiziol. Zh. (Kiev) 12(4):452-457, 1966.

Using 9 dogs prepared with fistulas of the mix salivary glands according to Pavlov-Glinsk and gastric fistulas according to Basov, it was fo that structures of the anterior gyrus zone and the amygdaloid nuclei (using stimulation with sinusoidal current of 0.1-1.5 milliamperes) participated in the regulation of the secretor function of salivary and gastric glands, and also in the secretion of gastric mucus. Stimu tion of the anterior gyrus zone with a current up to 1.0-1.5 milliamperes did not provoke sec tion from the salivary glands, but it caused secretion of a significant amount of gastric mucus. When secretion of an acid gastric juic preceded stimulation of the anterior gyrus zon stimulation stopped juice secretion and induce the secretion of gastric mucus. This stimulat markedly inhibited the histamine-induced secre tion of gastric juice and reduced its free- an total acidity (dogs received 0.0001 g/kg of histamine s.c., before or after stimulation). Therefore, stimulation of the anterior gyrus zone had no effect on salivation, inhibited secretory action of gastric glands, decreased the quantity of secretion, decreased acidity o the gastric juice and stimulated secretion of gastric mucus. A low stimulation (0.1-0.2 milliamperes) of the amygdaloid nuclei resulte in secretion of a significant quantity of sali and gastric mucus with a high lysozyme activit Brief stimulation of the amygdaloid nuclei by current of 0.5-0.7 milliamperes caused secreti of saliva and acid gastric juice with high enzymatic activity. Acid gastric juice was secreted after stimulation was discontinued, with max. secretion occurring in the interval between 15-45 min. after stimulation. Salivat reactions, which developed during stimulation the amygdaloid nuclei, were dependent upon the duration, force and frequency of the current employed. The greatest effects on salivation and the highest content of organic compounds i saliva were noted at a frequency of 40-60 hert and a force of 0.3-0.5 milliamperes. Prolonge stimulation by sinusoidal current provoked a

eater salivation during the first minute, which
en gradually decreased and ceased after 10-11
n.

055 GASTRIC SECRETION OF ACID AFTER INTRA-
VENOUS INFUSION OF HISTAMINE IN LARGE
SES. (E.) Dotevall, G. (Sahlgren's Hosp.,
teborg, Sweden) and A. Walan. Acta Med. Scand.
1(4):439-444, 1967.

histamine-infusion test with histamine (0.0084-
2520 mg/kg/hr.) admin. in increasing doses was
rformed on 18 patients with peptic ulcer for
e determination of the dose-response curve for
l produced by the stomach. The results were
mpared with secretory data obtained from the
me patients studied with the augmented histamine
st according to Kay, in which 0.024 mg of hist-
ine dihydrochloride was given. A half hr. before
stamine stimulation 100 mg of the antihistamine
tazoline was admin. i.m. The acid output was
atistically significantly higher with the
stamine-infusion test than with the Kay test.
e histamine-infusion test is simple and may be
value in studying the inhibitory effects of
fferent drugs on gastric secretion. This study
so corroborates the finding that the augmented
stamine test according to Kay does not give a
x. acid output with histamine as the only
imulator.

056 EFFECT OF STEROIDS ON GASTRIC MUCOSAL
STRUCTURE AND FUNCTION IN PERNICIOUS
EMIA. (E.) Rødbro, P. (Glostrup Hosp., Copen-
gen), H. Dige-Petersen, M. Schwartz and O. Z.
lgaard. Acta Med. Scand. 181(4):445-452, 1967.

ghteen patients (8 male, 10 female; mean age,
yr., with a range of 47-79) with Addisonian
rnicious anemia in remission were treated with
ednisone for 6 wk., 20 mg/day for 3 wk. and
mg/day for 3 wk. Before treatment 10 had
rietal cell antibody and 11 had intrinsic factor
tibody in serum. All patients were anacidic
fore and after treatment. The mean values for
cretory vol., conc. and hourly output of non-
trinsic factor vitamin B_{12}-binding capacity
fore and after steroid treatment were not sig-
ficantly different in either the basal or
imulated (histamine) periods. Before treatment,
very low mean conc. of intrinsic factor in
stric juice was found, and the hourly output in
e post-histamine hr. was below 100 U in all
ses; after treatment, there was a rise in in-
insic factor production sufficient for a normal
tamin B_{12}-absorption in 7 patients. A pre-
eatment biopsy study showed 3 patients with severe gastric atrophy, and 13 had a more or less pronounced atrophic gastritis, classified as moderate atrophy. After steroid treatment, the same picture of atrophic gastritis or gastric atrophy was noted, but 9 of 18 patients had normal gastric glands containing parietal cells in the atrophic mucosa. A fall in intrinsic-factor antibody titer of at least 20% of the value before treatment was found in 6 of 11 patients who had intrinsic-factor antibody in serum before treatment. A change in parietal cell antibody reaction from positive to negative or doubtful, regarded as a positive steroid effect on this antibody, was found in only 1 of 10 patients who had this antibody in their serum before treatment. The effect of steroids on gastric function and structure was in part found independently of gastric antibodies, which may well be a secondary phenomenon. It is doubtful that the finding of gastric antibodies constitutes support for the concept of pernicious anemia as an auto-immune disease.

11060 COMPARATIVE STUDY OF SECRETION OF INTESTINAL AND GASTRIC GLANDS DURING EMOTIONAL EXCITEMENT. (Uk.) Maevs'ka, N. V. (Donetsk Med. Inst., USSR). Fiziol. Zh. (Kiev) 13(3):408-411, 1967.

11061 EFFECT OF VAGOTOMY ON SECRETION. (It.)(Rev.) Speranza, V. (U. Rome) and A. Cirenei. Chir. Gastroent. (Roma) 1(2 Suppl.):272-277, 1967.

11062 NERVOUS CONTROL OF THE EXCHANGE OF NUCLEIC ACIDS AND PHOSPHATE LIPIDS IN THE TISSUE OF THE PANCREAS DURING SECRETION. (Pol.) Szostakowska, I. W. Ann. Univ. Curie Sklodowska [Med.] 20:349-363, 1966.

See also abstract nos.: 11444,11670,11931

11063 MOLECULAR WEIGHT AND AMINO ACID COMPOSITION OF HUMAN GASTRICSIN AND PEPSIN. (E.) Mills, J. N. (U. Oklahoma Sch. Med., Oklahoma City) and J. Tang. J. Biol. Chem. 242(13):3093-3097, 1967.

Molecular wt. for human pepsin and gastricsin were approx. 34,000 and 31,500, resp., as determined by the sedimentation-diffusion method, amino acid analysis data and sedimentation equilibrium studies. The sedimentation coefficients were found to be 3.14 Svedberg U for human pepsin and 3.32 Svedberg U for gastricsin. The sedimentation coefficient for gastricsin was conc.-dependent. The diffusion coefficients were found to be 8.7×10^{-7} cm^2 sec.$^{-1}$ and 9.6×10^{-7} cm^2 sec.$^{-1}$ for human pepsin and gastricsin, resp. The partial specific vol. calculated from the amino acid compositions were 0.724 ml/g for human pepsin and 0.724 ml/g for gastricsin. The amino acid composition of human pepsin was very similar to that of porcine pepsin. Human pepsin contained a significantly higher number of aspartic acid, isoleucine and serine residues than gastricsin, while the latter contained a significantly higher number of glutamic acid residues.

11064 PURIFICATION AND PROPERTIES OF PORCINE GASTRICSIN. (E.) Chiang, L. (U. Oklahoma Sch. Med., Oklahoma City), L. Sanchez-Chiang, J. N. Mills and I. Tang. J. Biol. Chem. 242(13):3098-3102, 1967.

The proteolytic enzyme, gastricsin, was isolated from an acidified extract of porcine gastric mucosa. The purification procedure consisted of ammonium sulfate precipitation followed by chromatography on columns of Amberlite CG-50 and Sephadex G-75. The enzyme preparation was found to be homogeneous on ultracentrifugation and electrophoresis. The enzymatic properties of porcine gastricsin, including optimal pH, hydrolysis of synthetic and protein substrates, milk-clotting activity and stability in an alkaline soln., were similar to those of the human gastricsin. Molecular wt. of porcine gastricsin was found to be 32,500. The amino acid composition of porcine gastricsin was similar to that of human gastricsin, and differed significantly from those of human and porcine pepsin.

11065 pH AND CONCENTRATION OF PANCREATIC ENZYMES IN ASPIRATES FROM THE HUMAN DUODENUM DURING DIGESTION OF A STANDARD MEAL IN PATIENTS WITH INTESTINAL DISORDERS. (E.) Worni H. (Blegdam Hosp., Aalborg, Denmark), S. Müllert E. H. Thaysen and H. O. Bang. Scand. J. Gastroe 2(2):81-89, 1967.

In 41 patients, intestinal contents were aspirat in 4 subsequent periods of 20 min. each after ingestion of a standard meal; the vol., pH and conc. of α-amylase, trypsin, chymotrypsin and lipase were determined in the collections. The patient material included 25 patients (13 men, 12 women) with gluten-induced enteropathy(including 5 with intestinal diverticula, 4 with regional enteritis, 3 with intestinal resection and 1 each with intestinal lymphosarcoma, Whipp disease, exudative jejunitis and intestinal lymphatic blockage and 16 with miscellaneous intestinal disorders). Only minor deviations from normal pH-levels were noted. In both grou of patients, lipase secretion, and to a minor degree that of amylase, were more markedly reduced than the secretion of the proteolytic enzymes. With the exception of the values of trypsin, conc. of enzymes were seen to be below the lowest normal value in approx. a third of the patients throughout the period of digestion It is concluded that the pancreatic function wa genuinely reduced in several patients with ente enous malabsorption, and that this may be expla as a nonspecific effect of malabsorption.

11066 PURIFICATION AND SOME PROPERTIES OF TH CATHEPSIN FROM THE SMALL INTESTINAL MUCOSA OF PIG. (E.) Kregar, I. (Stefan Nucl. Inst., Ljubljana, Yugoslavia), V. Turk and D. Lebez. Enzymologia 33(2):80-88, 1967.

MOTILITY

68 A METHOD FOR THE STUDY OF SPASMOLYTICS
IN VIVO ON THE ELECTRICALLY STIMULATED
BIT JEJUNUM. (Fr.) Lévy, J. C. (Albert-
land Lab., Chilly-Mazarin, France) and D.
Fel. Therapie 22(2):397-402, 1967.

rabbits (2.5-3.0 kg) anesthetized with
than were operated upon and a portion of
act jejunum was brought out (with unimpaired
od supply). A wire was used to support the
ion and it connected with a stylus; another
which was attached to this first one was
nected to a square-wave generator. A trocar
inserted s.c. into the flank of the animal
connected by wire to the other output post
he generator. A double-walled chamber, open
he top center for the connecting wire to the
us, surrounded the incision and body tempera-
of the preparation was maintained by circula-
of H_2O between the walls of the chamber which
retained H_2O in the tissues. The experimental
tem was calibrated at different square-wave fre-
ncies (10, 20, 50, and 100 cycles/sec. at 5, 10,
and 20 volts). Known spasmolytic substances
as atropine, papaverine, Novosparol, dipro-
ene and 1-n-butylscopolammonium bromide were
ted by i.v. and parenteral routes. Active
molytic agents reduced the amplitude of con-
tion. Thus atropine was active at 50 µg/kg
was 50% effective at 100 µg/kg; e.g., it re-
d the amplitude to 50%. Papaverine (10 µg/kg)
sed reduction of the amplitude by 50%. Atropine
active at a dose of 2 mg/kg parenterally. 1
-Butylscopolammonium bromide was active at a
of about 40 mg/kg. The active dosages are
rly higher than those found in vitro. The
ve doses/kg in the animal are about the size
he usual human dosages.

69 AN ANALYSIS OF THE SYMPATHOMIMETIC
EFFECTS OF ACETYLCHOLINE ON THE RAT
UM. (E.) Gokhale, S. D. (Med. Coll., Baroda,
a), O. D. Gulati and D. I. Panchal. Brit. J.
rmacol. 30(1):35-45, 1967.

ated ileal segments from starved, healthy
were suspended in a bath containing hyoscine
g/ml) at 37°C. Distinct, dose-related in-
tion of ileal tone and movement resulted from
ylcholine admin. in conc. of 4-8 µg/ml. Fur-
evaluation of acetylcholine activity was con-
ted employing a drug conc. of 6 µg/ml. Pron-
lol (5 µg/ml) or phentolamine (10 µg/ml)
ially inhibited acetylcholine response, whereas
ther they totally inhibited ileal response to
ylcholine. Bretylium, guanethidine and xylo-
ine, all in conc. of 20 µg/ml, blocked acetyl-
ine inhibition, but such inhibitory action
lf was blocked by admin. of dexamphetamine
methylamphetamine. Pretreatment with re-
ine blocked the effect of acetylcholine, which
then restored by norepinephrine admin.
g/ml). In addition, fully restored acetyl-
ine response was blocked by bretylium, xylo-
ine and guanethidine. Hexamethonium (10 µg/ml), pempidine (5 µg/ml) and mecamylamine (5 µg/ml) potentiated the effects of both acetylcholine and norepinephrine, but fully inhibited nicotine responses. Cocaine (10 µg/ml) did not affect acetylcholine response. These findings demonstrate the similarity between acetylcholine admin. and sympathetic stimulation in the rat ileum and suggest a cholinergic link between the sympathetic impulse and norepinephrine release.

11070 AN ANALYSIS OF THE AUTONOMIC CONTROL OF GASTROINTESTINAL MOTILITY IN THE CAT. (E.) Neely, J. (St. Bartholomew's Hosp., London) and B. N. Catchpole. Gut 8(3):230-241, 1967.

When cats were infused with neostigmine at a slow rate to stimulate gastrointestinal motility, the colon was most sensitive to the drug, the stomach less so, and the small intestine least. Under neostigmine stimulation there was no significant difference in the inhibitory effects of norepinephrine on these 3 areas. However, the colon was most sensitive to isoprenaline, the stomach less and the small intestine least. In cats which received an α-adrenergic blockade (phenoxybenzamine) prior to neostigmine, the small intestine became more sensitive to the latter drug and the colon more resistant relative to the stomach. Use of β-adrenergic blockade (propranolol) did not greatly alter the response to neostigmine. After phenoxybenzamine and atropine, the infusion of propranolol produced an almost consistent increase in colonic activity, but had less effect on the small intestine and virtually none on the stomach. Blockade of the sympathetics with guanethidine increased the activity of the small intestine even in the presence of β-adrenergic block. The vagotomized stomach was resistant to the action of physostigmine; the resistance of the small intestine and colon were increased. It is concluded that the stomach has a high level of extrinsic and a low level of intrinsic cholinergic control; both α and β-adrenergic receptors are present; the small intestine has a low level of extrinsic control and an intrinsic cholinergic control with sympathetic mediation mostly through α-receptors; and the colon has a low degree of cholinergic control and a sympathetic inhibition mediated mainly by β-receptors.

11071 DIRECT AND INDIRECT STIMULATION OF THE INTESTINES IN PATIENTS WITH TRAUMATIC SEVERANCE OF THE SPINAL CORD. (Rus.) Vishnevskii, A. A. (Vishnevsk Inst. Surg., Moscow), A. V. Livshits and B. I. Khodorov. Eksp. Khir. Anest. 12(3):8-11, 1967.

Direct and indirect stimulation of the intestine was studied in 2 men (19 and 20 yr. old) with complete traumatic interruption of the spinal cord 7 and 6 mo. earlier, resp. In 1 of the 2 patients surgery was concluded by implantation of a radio frequency receiver under the abdominal wall and by platinum electrodes introduced in the bladder. In the other, a negative electrode was induced into the rectum and a positive one placed on the abdominal wall. Electric stimulation of the bladder (10-15 volts, 1 msec., frequency 20 cycles/sec.) caused stimulation of intestinal peristalsis and restoration of the act of defecation. Direct stimulation of the intestine with electric impulses (10-30 volts, 5-7 msec., 10-20 cycles/sec.) led to stimulation of intestinal peristalsis, manifested by an increase of motility and electric activity. Indirect and direct electric stimulation of the intestine provoked reflex activation of the parasympathetic nervous center which regulates intestinal peristalsis.

11072 BEHAVIOR OF THE INTERSTITIAL TEMPERATURE IN EXPERIMENTS ON MECHANICAL INTESTINAL OCCLUSION. (Pol.) Tołłoczko, A. (First. Surg. Inst., Acad. Med., Bialystok, Poland) and A. Obrzut. Przegl. Lek. 22(6):465-468, 1966.

The decrease of interstitial temperature in the small intestine during experimentally-induced occlusion was measured in 10 dogs. In 30 cm of exposed small intestinal loop a segment was tied off in 2 places to create an occlusion; air was introduced through a cannula and the air pressure measured with a manometer. Temperature was measured within 30 min. of exposure while the surrounding temperature was kept at 25-30°C. The electrodes of the thermometer were applied interstitially in the muscular layer of the intestinal wall. Measurements were made every min. for 10 min. varying the intraintestinal pressure between 10 and 40 mm Hg and also after release of the pressure. The i.m. temperature of the small intestine decreased 0.6-4.7°C within 1-6 min. depending on the amount of pressure applied. Temperature returned to normal 2-8 min. after removing the intestinal pressure. It is suggested that the speed with which the temperature decreased indicates that extensive disruption of the capillary circulation occurs even during mild dilatation of the small intestine.

11073 STUDIES ON THE VOMITING CENTER; THE LOCALIZATION OF THE RETCHING RESPONSIVE AREA IN THE MEDULLA AND PONS. (E.) Kimura, N. (Hiroshima U. Sch. Med., Japan). Hiroshima J. Med. Sci. 15(2):171-178, 1967.

Retching movements in response to electrical stimulation were recorded in 23 dogs as internal pressure variations of the stomach and distal colon, and systemic blood pressure was simulaneously recorded in the right common carotid artery. Retching was followed by changes in systemic blood pressure (rise or fall) and the increase or decrease in the peristaltic movement of the stomach and distal colon, but no correlation between retching and other autonomic reactions could be determined. Retching was induced both in the anesthetized dog and in the nonanesthetized decerebrated dog; retching was also elicited in the vagotomized dog and also in the spinal dog whose spinal cord was transected between the cervical and thoracic region. A total of 45 retching responsive points were found in the medulla oblongata; these were the dorsolateral nucleus of the vagus nerve (10 points), dorsomedial nucleus of the vagus nerve (9 points), nucleus of the medial solitary tract (4), nucleus of the inferior solitary tract (4), nucleus of the lateral solitary tract (3), the tractus solitari (6), reticular formation (7), internal arcuate fibers (1) and nucleus intercalatus (1). Only 3 retching points were found in the pons; these were the lateral vestibular nucleus, rubrospinal tract and fibers of the vagus nerve. The latte finding suggests that the medulla oblongata is more responsible than the pons as the retching center.

11074 RELEASE OF 5-HYDROXYTRYPTAMINE FROM ISOLATED DOG INTESTINE BY NICOTINE. (E.) Burks, T. F. (U. New Mexico, Albuquerque) and J. P. Long. Brit. J. Pharmacol. 30(2):229-239, 1967.

The release of 5-hydroxytryptamine from dog small intestine segments perfused with Krebs bicarbonate soln. was enhanced by both nicotine and dimethylphenylpiperazinium; these agents al initiated contractions of the intestinal smooth muscle. The enhanced 5-hydroxytryptamine relea and intestinal contraction produced by nicotine and acetylcholine were significantly antagonize by atropine. Perfusion of the isolated intesti sections with Ca-free soln. reversibly abolishe the smooth muscle responses to nicotine and diminished responses to 5-hydroxytryptamine and morphine; there was a smaller but still signifi diminution of the responses to acetylcholine. The increase in intestinal motility by 10 µg of nicotine and 2 µg of dimethylphenylpiperazinium was not antagonized by 100 µg of hexamethonium; there was an insignificant increase in the response to nicotine after treatment with hexamethonium. Both nicotine and dimethylphenylpiperazinium were significantly antagonized on the isolated intestinal sections by 500 µg dose of nicotine. The ability of 100 µg of hexamethonium to depress the parasympathetic gangli in an in situ intestinal section was shown by locally antagonizing intestinal responses to vagal stimulation. Nicotine and dimethylphenyl piperazinium could have enhanced release of 5-hydroxytryptamine and intestinal motility in th preparation by stimulation of extraganglionic nervous structures, by direct action on the cholinergic receptors or, perhaps more likely, stimulating a population of ganglion cells whic are exceptionally resistant to hexamethonium blockade.

11075 EFFECT OF HEMORRHAGE-INDUCED ANEMIC HYPOXIA ON PROPULSIVE MOTILITY OF THE SMALL INTESTINE IN CATS. (E.) Li, Y.-S. (Nat. Taiwan U., Taipei) and H.-S. Fang. J. Formosa Med. Ass. 66(6):308-311, 1967.

LIBRARY U. OF I. URBANA-CHAMPAIGN

ts previously fasted for 24 hr. were subjected 2 experimental procedures using the charcoal- rker method. In Procedure A, a charcoal mixture s admin. by stomach tube; 5 min. after this the imal was anesthetized with nembutal i.v. and bjected to a massive hemorrhage (removal of 40% the blood vol.); after 40 min. the animals re sacrificed and the distance which the charcoal xture had traversed the small intestine was asured. In Procedure B, the cats were first esthetized and the charcoal-mixture was inj. rectly into the proximal duodenum after it had en exposed at laparotomy. These animals were en subjected to massive hemorrhage (removal of % of the blood vol.), and 2 hr. after charcoal j. the animals were sacrificed. With both ocedures the control animals were treated entically, except that no hemorrhage was induced. e charcoal mixture moved much more quickly along e small intestine in animals treated by Procedure than by Procedure B. Severe anemic hypoxia oduced a reduction in motility to an av. of 32% the intestine traversed in Procedure A, compared 48% for controls treated by this procedure; those treated with Procedure B, motility was duced to 17% of the intestine traversed, as mpared to 36% in controls treated with this ocedure. Thus, hemorrhage-induced anemic poxia caused a significant decrease in intestinal opulsive motility of the cat. These results ffer from those obtained in the dog by other vestigators in which hemorrhage-induced anemic poxia caused an increase in propulsive motility the small intestine.

076 FORCE IN THE ANAL CANAL AND ANAL
CONTINENCE. (E.) Collins, C. D. (Roy.
firm., Sheffield, England), H. L. Duthie, T.
elley and G. E. Whittaker. Gut 8(4):354-360,
67.

17 normal fully-continent subjects (all male; -70 yr. old), the radial force exerted by ueezing of the anal sphincters and pressure in e anal canal were measured at the same time as ectrical activity in the external anal sphincter. l 3 parameters gave similar responses at rest, coughing or voluntary squeeze of the perianal scles. On a Valsalva maneuver, the changes in rce were less than those of pressure, especially the upper anal canal. When the rectum was stended with a balloon, the well-known decrease pressure in the anal canal was not accompanied any definite change in force. On the basis of ese results, it is suggested that mechanical ctors rather than muscular relaxation may play important part in the responses in the anal nal.

077 A STUDY OF THE INNERVATION OF THE
TAENIA COLI. (E.) Bennett, M. R.
. Melbourne, Australia) and D. G. Rogers. J.
ll Biol. 33(3):573-596, 1967.

e anatomical features and the electrophysiological tivity of the guinea pig taenia coli was studied. Changing the membrane potential of single cells cannot modulate the rate of firing action potentials although electrical coupling between the cells during propagation occurred. The amplitude of the junction potentials which occur during transmission from inhibitory nerves was not affected, thus indicating electrical coupling during transmission. The taenia coli is composed of smooth muscle bundles which anastomose. Tight junctions between cells in the bundles supply a pathway for the electrical coupling. Smooth muscle cells toward the serosal surface have an extensive intramural inhibitory innervation, although a weak sympathetic inhibitory and cholinergic excitatory innervation exists. These data agree with the distribution of these nerves as determined histochemically. The only muscle cells which undergo permeability changes during transmission are those adjacent to varicosities in the nerve bundles. This conclusion is due to the fact that single axons are rarely observed in the taenia coli. It is assumed that the remaining muscle cells then undergo potential changes during transmission because of electrical coupling through the tight junctions.

11078 BIOELECTRIC REACTIONS OF HYPOTHALAMIC
REGION BY CHEMICAL STIMULATION OF
SMALL INTESTINE RECEPTORS. (Rus.) Udalova, G. P.
Nerv. Sist. (Leningr.) (7):83-88, 1967.

In 14 rats the small intestine was stimulated by NaCl soln. (2.5-15% soln.) or HCl (0.25-1.0% soln.) inducing changes in the bioelectric activity of the hypothalamus. The clearest reaction was observed in the region of the ventro-medial nucleus. NaCl (5-15%) or HCl (0.5-1.0%) evoked potentials with initial positive, and, subsequently, slower negative phases, 0.2-0.5 sec. after entrance into the intestinal loop; its duration was 100-200 msec., and the amplitude was 50-80 μvolts. Such potentials could be absent during repeated stimulations; 1.5-5.0 sec. after initiation of admin., of soln. a series of 3-7 potentials arose followed by intervals of 2-10 sec. In this series, in addition to biphasic potentials, also single (more often positive) and multiphase potentials were noted with an amplitude of 100-200 μvolts and a duration of 150-500 msec. NaCl (2.5%) and HCl (0.25%) in lower conc. caused no evident changes or, gave a slight effect, and had no effect on the electrical activity of the hypothalamus. The type of response depended upon the depth of narcosis, pentobarbital-Na, conc. of soln., duration of their presence in the intestinal loop, and also on the sequence of the use of stimulants. Under light narcosis, stimulation with NaCl or HCl was followed by only basic changes of hypothalamic activity, while after deep narcosis, basic changes and the above potentials were found. Presence of the soln. in the intestinal loop for 20-60 sec. caused a reaction while a more prolonged stay caused weakening of the stimulation.

Repeated admin. of the soln. (3-4 times) weakened the response in the electrical activity of the hypothalamus; however, repeated action of chemical stimulants and washing with physiological soln. caused (after 5-6 admin.) an irregular rhythmic sequence, variations in amplitude and frequency, and the appearance of spontaneous potentials similar to those which appeared after the use of NaCl or HCl. Admin. of physiological soln. did not induce these potentials; if physiological soln. was given immediately after the appearance of potentials (on admin. of NaCl or HCl), they disappeared. This difference in reaction to NaCl or HCl and physiological soln. disappeared during deep narcosis. Procaine (0.5-1.0%) temporarily removed the response in the electrical activity of the hypothalamis, of the action of chemicals on intestinal receptors. The response, under conditions of simultaneous recording, was less significant in the preoptic region than in the ventromedial nucleus. Response to NaCl or HCl in the lateral region of the hypothalamus was very low or absent and the reaction of the mamillary bodies on stimulation was not clear. Mechanical stimulation in the form of a single inflation of the intestine had no effect or response occurred only at the start of inflation; no potential series was shown.

11079 SONIC CORRELATES OF HUMAN DEGLUTITION. (E.) Logan, W. J. (NIH, Bethesda, Md. J. F. Kavanagh and A. W. Wornall. J. Appl. Physiol. 23(2):279-284, 1967.

11080 ENDOGENOUS CHOLECYSTOKININ AND THE CONTRACTION OF THE GALLBLADDER. (Jap. Ariyama, J. (Juntendo U. Sch. Med., Japan). Nippon Naika Gakkai Zasshi (J. Jap. Soc. Intern. Med.) 56(3):252-259, 1967.

)83 EFFECT OF BILIARY DRAINAGE ON INDIVIDUAL
REACTIONS IN THE CONVERSION OF CHOLESTEROL
TAUROCHOLIC ACID. BILE ACIDS AND STEROIDS 180.
) Danielsson, H. (Karolinska Inst., Stockholm),
Einarsson and G. Johansson. Europ. J. Biochem.
):44-49, 1967.

effect of biliary drainage on incorporation
acetate into cholesterol and on 4 different
yme systems in the metabolic pathway from
lesterol to taurocholic acid was studied in
ogenates of liver from male Sprague-Dawley rats.
homogenates of liver taken from bile fistula
s, 48 hr. after operation, the extent of in-
poration of acetate into cholesterol was approx.
fold greater and the extent of 7α-hydroxylation
cholesterol approx. 8-fold greater than in
ogenates of liver from control animals. The
er reactions studied, namely the conversion of
lest-5-ene-3β,7α-diol to 7α-hydroxycholest-4-
3-one, the 12α-hydroxylation of 7α-hydroxy-
lest-4-en-3-one, and the 7α-hydroxylation of
rodeoxycholic acid, were influenced much less
biliary drainage. It is suggested that the
roxylation of cholesterol to cholest-5-ene-
7α-diol might be a rate-determining step in
conversion of cholesterol to bile acids.

34 COMPOSITION OF HUMAN HEPATIC BILE. (E.)
van der Linden, W. (U. Umeå, Danderyd,
den) and A. Norman. Acta Chir. Scand. 133(4):
-313, 1967.

ing operations for gallstone disease, bile
bles were taken from the common bile duct in
patients (28 men, 73 women) under standardized
ditions. The conc. of cholesterol, phospho-
ids, bilirubin and total solids were determined.
siderable variations were found in the conc.
the different bile constituents. Comparisons
age and sex revealed no significant differences,
could any relationship be established between
cholesterol conc. in bile and serum. Com-
son of the first bile sample obtained immed-
ely after ligation of the cystic duct with
second and final sample revealed a difference
veen cases with a functioning gallbladder and
se with a nonfunctioning gallbladder; in most
es of the former group, the amount of total
ds was greater in the first sample, while the
osite was true in most cases of the latter
up. Differences between first and second
ple seemed to be larger in the group with a
ctioning gallbladder than in the group without.
ther analysis of the decrease with time in the
up with a functioning gallbladder showed that
of the investigated bile constituents were
olved; significant differences between the
t and second sample were found for total
ds, phospholipids and cholesterol, but the
ference for bilirubin did not approach the
el of significance. The wt. ratio phospho-
ds:cholesterol was highly variable, ranging
0-10.7. The significance of these results for the present concept of the physicochemical mechanism by which cholesterol is kept in soln. is discussed. It is concluded that liver cells which excrete cholesterol into the blood as lipoproteins with a relatively fixed ratio cholesterol:phospholipids, excrete cholesterol and phospholipids into the bile with a considerably less obvious ratio and that bile may hold cholesterol in soln. with very little or no phospholipids.

11085 TWO SITES OF BILE FORMATION AS DETERMINED BY MANNITOL AND ERYTHRITOL CLEARANCE IN THE GUINEA PIG. (E.) Forker, E. L. (U. Iowa, Iowa City). J. Clin. Invest. 46(7):1189-1195, 1967.

Guinea pigs were admin. a single i.v. inj. of 3 μc of erythritol-^{14}C and 15 μc of mannitol-$^{3}H_2$ and to some additional unlabeled mannitol or erythritol to give a final plasma level of 5 mM/liter to study the relationship of biliary clearance to the rate of bile flow and the molecular size of the test solute after admin. of approx. 100 mg of dehydrocholate or 5 U of secretin. Following biliary clearance, the mean increment in bile flow after secretin was only half that seen with dehydrocholate. The av. decline in plasma level expressed as a percentage of the initial value was 7 ± 6% for erythritol and 5 ± 4% for mannitol. The 700-fold increase in plasma level of mannitol or erythritol did not result in reduced clearance of either product. Mannitol had limited access to muscle; it invaded hepatic H_2O almost completely; whereas erythritol approached an equilibrium in both tissues. Spontaneously flowing bile contained 57 ± 4 mEq/liter of bicarbonate which fell to 40 after dehydrocholate and rose to 76 mEq/liter after secretin. The changes in clearance produced by dehydrocholate suggested that osmotic filtration rather than diffusion is the predominant mode of transfer for mannitol and erythritol. The mechanism appeared to effect a net secretion or reabsorption of fluid at a rate roughly proportional to the rate of flow in the canaliculi.

11086 INCORPORATION OF PLASMA FREE FATTY ACIDS INTO BILE LIPIDS IN MAN. (E.) Scherstén, T. (U. Goteborg, Sweden), A. Gottfries, S. Nilsson and B. Samuelsson. Life Sci. 6(16):1775-1780, 1967.

Two male patients, 47 and 58 yr. old, operated upon for cholelithiasis and who had clinically normal liver function, were used to study the incorporation of plasma free fatty acids into human bile lipids. The experiment was performed 6 days after surgery, during which time the enterohepatic circulation was maintained intact. The patient was fasted for 12-15 hr. before the study and was kept afasting during the first 8 hr. of the experiment. Human albumin-complexed palmitate-1-^{14}C was infused into a femoral artery at a constant rate of 0.15-0.18 µc/min. during 1 hr.; samples of blood and bile were collected and analyzed. The turnover rate of plasma free fatty acid C was 12.3 and 14.4 mmoles/min., resp., in the 2 patients. The rise of radioactivity in plasma triglyceride fatty acids and in bile phospholipid fatty acids was parallel and rapid in both subjects. Max. activity was attained in approx. 2 hr. Incorporation of plasma free fatty acids into bile phospholipids occurred almost exclusively into lecithin. In spite of the high content of phospholipid in the liver, a rapid secretion of phospholipids with high specific activity into the bile occurred after infusion of 1-^{14}C-palmitate into the plasma, indicating mixing of radioactivity in the small phospholipid pool in the liver before excretion into the bile. Traces of radioactivity were also found in plasma phospholipids and in bile cholesterol.

11087 THE ACCUMULATION OF TISSUE CHOLESTEROL AND ITS RELATIONSHIP TO BILE ACID AND STEROL TURNOVER. (E.) Beher, W. T. (Edsel B. Ford Inst. Med. Res., Detroit, Mich.), B. Rao, M. E. Beher, G. Semenuk, J. Bertasius and N. Vulpetti. Henry Ford Hosp. Med. J. 15(2):107-118, 1967.

Normal and hypophysectomized rats were divided into equal homogeneous groups to determine the effect of cholestyramine, corn oil and cholesterol on the excretion of fecal bile acids and sterols. Bile-acid-turnover rates, pool sizes and spectrums were studied and compared. Study of the effects of dietary cholesterol and corn oil revealed that cholesterol greatly increased the rate of conversion of liver sterols to bile acids by increasing the rate of elimination of bile acids from their pool. Also, while cholesterol had little effect on the size of the bile acid pool, it increased the proportion of chenodeoxycholic acid. Corn oil had no effect on bile acid metabolism. The increased output of bile acids as influenced by dietary cholesterol constituted a defense mechanism which protected the rat from excess dietary cholesterol. A comparative study of the accumulation of tissue cholesterol of dietary origin in normal and hypophysectomized rats showed that the latter accumulated much more blood and liver cholesterol than normal rats when fed cholesterol-containing diets. Further study showed that the bile acid turnover rate was much slower in hypophysectomized rats than in normals. Bile acid synthesis was much reduced, since these animals had relatively normal bile-acid-pool sizes. The bile acid pool of hypophysectomized rats contained much less chenodeoxycholic acid than the pools of normal rats. A comparative study of cholesterol and coprostanol excretion showed that hypophysectomized rats excreted much smaller quantities of these fecal sterols than normal rats. The hypophysectomized rat was thus relatively unable to handle excess body sterols. Cholestyramine, an insoluble bile acid-binding polymer, was effective in preventing accumulation of tissue cholesterol in normal and hypophysect ized animals, when it was fed along with athero genic diets. This resin greatly increased the turnover rate of bile acids and their synthesis in both types of rats; it had no effect on the size of the bile acid pools.

11088 EFFECT OF PHENOBARBITAL ON THE EXCRET OF AN EXOGENOUS BILIRUBIN LOAD. (E.) Roberts, R. J. (U. Iowa Coll. Med., Iowa City) and G. L. Plaa. Biochem. Pharmacol. 16(5):827-835, 1967.

Treatment of male Swiss-Webster mice with pheno barbital significantly enhanced the disappearan of exogenously admin. bilirubin from the plasma This enhanced disappearance not only occurred i the absence of biliary excretion, but it was ac companied by liver bilirubin conc. exceeding th found in control animals. Both observations su gest enhanced uptake of free bilirubin by the liver as 1 cause of the faster rate of disappea of bilirubin from the plasma. In male Simonsen rats, the max. rate of bilirubin excretion was enhanced by treatment with phenobarbital. Bile vol. was also greater in phenobarbital-treated rats than in control animals. The conc. of bi rubin in the bile was not significantly differe indicating that the increase in bilirubin excre tion was probably due to the increase in bile Indirectly, some of the data suggest that increased bilirubin conjugation may play a role the enhanced uptake and excretion of bilirubin after phenobarbital treatment.

11089 THE DEVELOPMENT OF RADIOACTIVITY IN THE LIVER AFTER THE INJECTION OF RADIOACTIVE ALBUMIN TO DETERMINE HEPATIC CIRCULATORY RATE. (Fr.) Silva Carvalho, J. (Fac Med., Lisbon). C.R. Soc. Biol. (Paris) 161(1) 210-213, 1967.

Of 26 subjects, 4 were normal, 6 had cerebral thromboses, and 16 had diseases with no relati to hepatic circulation; each received i.v. inj of 10-15 µg of ^{131}I-albumin. The radioactivit of the liver and spleen was measured for 1-3 h using a scintillation counter and graphic reco ings. Some sec. after admin. of the ^{131}I-albu radioactivity of the liver increased rapidly a reached a max. value after 10 min. This incre corresponded to the fixation of the radioprote by the Kupffer cells. The av. constant of fix tion was 0.310/min. Following a period of 6-1 min. during which the radioactivity of the liv was at a dynamic max. (gain equal to loss), th radioactivity diminished exponentially in 2 phases, the first about 35 min. and the second with lesser slope, about 105 min. The radioactivity of the spleen was weak thus indicatin a phagocytic activity inferior to that of the liver.

11090 ALBUMIN CONTENT OF RAT HEPATIC CELLS AT DIFFERENT LEVELS OF PROTEIN INTAK

.) Chandrasakharam, N. (U. Malaya, Kuala
mpur), A. Fleck and H. N. Munro. J. Nutr.
(4):497-502, 1967.

study was performed to determine whether the
otein content of the diet affects serum albumin
nthesis by regulating the number of liver cells
tively producing albumin. A fluorescent anti-
rum was prepared against rat albumin and used
r identification of liver cells containing
bumin. Young adult albino male rats were used.
ntrols were fed a stock diet containing 16%
otein. Others were fed either a protein-rich
et, containing 28.5% casein, 41.8% potato starch
d 15% glucose, or a protein-free diet, contain-
g 64% starch and 21% glucose. Both of these
ets also included 5% margarine fat and 10% of a
tamin-mineral-roughage mixture. All diets were
d for 4 days. The number of albumin-containing
lls in the liver was greatest when animals were
d a diet rich in protein; the numbers were inter-
diate when maintained with a stock diet; and
e number was very infrequent when the diet was
void of protein. Deprivation of protein or
eding a protein-rich diet for 4 days had no
gnificant effect on total conc. of protein in
asma, but there was a significant reduction in
asma albumin conc. in the group deprived of
otein. This study confirms that the level of
asma albumin is a more sensitive index than
e level of total plasma protein to deficiency
dietary protein. Protein deficiency decreased
th the plasma albumin level and the total pro-
in conc. in liver to approx. 20% below the level
tained with animals fed the high-protein diet.

091 INVESTIGATION OF HEPATIC DRUG METABOLISM
BY ISOLATED PERFUSED LIVER IN SITU.
.) Benzi, G. (Pavia and Pisa U., Italy), F.
rté and A. Crema. J. Pharm. Sci. 56(7):893-895,
67.

olated and perfused livers in dogs and monkeys,
which blood circulation was maintained by an
tracorporeal pump-oxygenator system, were
aluated with respect to the metabolism of amino-
rine and oxazepam. This study involved the
sessment of demethylation by evaluating the
ansformation of aminopyrine to 4-aminoantipyrine;
etylation by studying the change of 4-amino-
tipyrine to N-acetyl-4-aminoantipyrine and
nally the capacity for glucurono-conjugation by
serving the transformation of oxazepam to
ucuronide. During the perfusion period (2-3
.) no change in SGPT, sorbitol dehydrogenase,
ucine aminopeptidase and BSP time was noted
ile a slight linear increase in SGOT was ob-
rved. The disappearance of both aminopyrine
d oxazepam from the extracorporeal blood was
oid for both dog and monkey. The half-life for
inopyrine was 10-14 min. and 16-20 min. for the
g and monkey, resp., while the half-life for
azepam was 7-10 min. for both animals. De-
thylation activity was very similar in both
e dog and monkey liver. Acetylation was higher
the monkey as compared to the dog. Liver conc.
of 4-aminoantipyrine was similar in both dog and monkey, whereas the liver conc. of N-acetyl-4-aminoantipyrine was higher in the monkey. These findings suggest that this method of isolated liver perfusion may be helpful in assessing liver metabolism in situ.

11092 THE RESPIRATION OF HUMAN LIVER TISSUE. (E.) Booth, J. (Roy. Cancer Hosp., London), E. Boyland and C. Cooling. Biochem. Pharmacol. 16(4):721-724, 1967.

The rate of O_2 uptake (measured in standard Warburg vessels at 37°) was determined in rat (adult Chester Beatty strain) and human liver slices in various media. The incubation media included 1) Krebs-Ringer phosphate; 2) Krebs medium II, type A, which contained pyruvate (4.9 mM), fumarate (5.4 mM) and glutamate (4.9 mM); and 3) Krebs-Ringer phosphate containing succinate (20 mM). All media contained glucose (11.5 mM). The results showed that the O_2 uptake was higher in rat liver than in human liver in all media used and that the difference was greatest when glucose was the only added substrate. Under these conditions the ratio of the mean values for the respiration of rat liver and human liver was 3.9 (9.0/2.3). The O_2 consumption (μliters/mg dry wt./hr.) for man and rat, resp., in each of the 3 incubation media were as follows: 1) Krebs-Ringer phosphate: 2.3 ± 0.3, and 9.0 ± 0.9; 2) Krebs medium II, type A, 6.3 ± 0.7 and 13.8 ± 1.6; and 3) Krebs-Ringer phosphate containing succinate: 24.9 ± 3.9 and 27.7 ± 4.8. It is concluded that the rate of respiration of liver from various species (including man) decreases with increase in body wt., so that the respiratory rate is approx. inversely proportional to the logarithm of the body wt.

11093 EFFECT OF HYPOGLYCEMIC AGENTS ON LIVER REGENERATION. (E.) Gershbein, L. L. (Northwest Inst. Med. Res., Chicago, Ill.). Biochem. Pharmacol. 16(6):1117-1120, 1967.

The effect of therapeutic doses of sulfonylurea and biguanide derivatives (tolbutamide, chlorpropamide, acetohexamide, phenformin·HCl, insulin NPH, glucagon and depropanex) on liver regeneration in partially hepatectomized rats and the long-term effects of prolonged systemic hypoglycemia is reported. Acetohexamide and chlorpropamide depressed liver regeneration at levels of 0.75 and 0.15%, resp. Chlorpropamide at conc. of 0.015% was without effect, but with conc. of 0.40% a marked inhibition of regeneration was observed. Tolbutamide in very large doses did not affect regeneration. The sulfonylureas lost their effect when pancreatectomy was carried out. Phenformin·HCl was a marked inhibitor at both 0.075 and 0.15% conc. Insulin NPH in conc. of 3.3 U/kg daily for 7 days was without effect on regeneration as also was that of glucagon and depropanex. The described inhibitory effects also applied to pair-fed series. It is not certain, according to the authors, whether the observed inhibitory effects by both the sulfonylureas and the biguanides represent a common drug mechanism or whether these drugs act on the regenerating liver at a higher pharmacological level. The possibility that these agents evoke an amino acid antagonism or inhibition of protein synthesis in the regeneration of the liver is suggested for consideration.

11094 STUDIES ON INFLUENCE OF ESTROGEN ON LIPID METABOLISM FOLLOWING PARTIAL RESECTION OF LIVER. (E.) Miyaura, Y. (Kyoto U. Med. Sch. Hosp., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 36(3):195-223, 1967.

The effect of estrogen (10 μg/100 g inj. i.m. 7 days before partial hepatectomy) on liver regeneration and lipid metabolism after partial resection of the liver was studied in (male Saitama strain) rats, and compared with rats who did not receive the hormone. Increase in body wt. after partial resection of the liver was more rapid in the group that received estrogen, showing restoration of body wt. to the preoperative level to be 5 days after surgery. The rate of increase in liver wt. after partial resection was very rapid in estrogen-treated rats, as compared with non-estrogen-treated animals, and the difference of the rate between these 2 groups was most marked 2-3 days after operation when liver regeneration is at its max. Each fraction of intrahepatic lipids showed a max. level 10 hr. after partial resection, which was followed by restoration to the preoperative level 5 days postoperatively; each lipid fraction was invariably lower in the estrogen-treated group; this was particularly seen in the fractions of intrahepatic total fatty acids, neutral fat and total lipids. The intrahepatic esterified cholesterol:total:cholesterol ratio and the total cholesterol:total phospholipids ratio showed a slight increase temporarily after partial resection; however, there was little significant difference between estrogen-treated and non-estrogen-treated rats. Lipid fractions in the blood (especially total phospholipids and neutral fat) showed a tendency to increase after partial resection, whereas total cholesterol and esterified cholesterol decreased. Free cholesterol, total fatty acids and total lipids showed little fluctuation throughout the pre- and postoperative period. In the group that received estrogen, contents of total phospholipids, total fatty acids, neutral fat and total lipids in the blood were considerably higher than in the non-estrogen-treated group; the reverse prevailed for free cholesterol, esterified cholesterol and total cholesterol. In blood, the esterified cholesterol:total cholesterol ratio and total cholesterol:total phospholipids ratio showed a tendency to decrease after partial resection, and the ratios were invariably lower in estrogen-treated animals. The content of nonesterified fatty acids tended to increase after operation in both groups; the content was smaller in estrogen-treated animals. Histological examination showed no significant difference between the groups. From these results it is c cluded that admin. of estrogen enhances regener tion of the residual liver parenchyma after par tial hepatectomy and inhibits accumulation of f within the liver. Stated differently, the effe of estrogen are to inhibit release of nonesteri fatty acids from the peripheral adipose tissue, to inhibit synthesis of cholesterol within the liver, and to enhance release of neutral fat in the blood stream (which are the results of increased synthesis of phospholipid within the liver).

11095 THE EFFECT OF TESTOSTERONE IN PARTIAL HEPATECTOMIZED FEMALE RATS. (E.) Bengmark, S. (U. Goteborg, Sweden), R. Olsson and B. Rehnstrom. Scand. J. Gastroent. 2(2): 90-94, 1967.

The influence of testosterone treatment on live regeneration after partial hepatectomy was stud in female Sprague-Dawley rats, treated with testosterone-3-(p-hexyloxyphenyl)-propionate (8 admin. i.m.), a long-acting testosterone prepar tion. The rats had been fed a commercial diet of the following composition: crude protein, 23%; carbohydrate, 52%; fat, 4%; ash, 10%; wate 11%; vitamins and salts. The animals were sacrificed 8 days after operation. No influence o the hormone was observed on liver wt. restorati The treatment lowered the liver N conc. before well as after the operation, and the RNA conc. before the operation. It did not influence the postoperative decrease in serum albumin and a α-1-globulin, but caused an increased conc. of α-2-globulin before the operation and of β-2-globulin after the operation. There thus was n evidence of an anabolic effect of the testoster admin. on the liver.

11096 IMPORTANCE OF THE SENSORY NEURONS FOR THE MAINTENANCE OF STRUCTURAL AND FUNCTIONAL INTEGRITY OF THE LIVER. (Rus.) Astakhova, A. M. (2nd Pirogov Med. Inst., Mosco Arkh. Anat. 52(7):104-106, 1967.

Cytological examination of parenchymatous cells of liver with severed afferent nerves showed al signs of a disturbance of secretory process whi occurred early and late in the experiment. During the first mo. after removal of the sensory nodes in the hepatic lobes some cells were overloaded by secretory granules, some contained fe granules, and the cytoplasm of some was complet empty. At a later period after surgical denerva tion all hepatic cells were depleted of secreto granules. Golgi apparatus at different times o denervation showed changes in its location and structure in different parts of the hepatic lobes. In the cells loaded by secretory granul elements of Golgi apparatus had a fine-grained character and were located in the cytoplasm between the secretory granules; in the cells poor with such granules Golgi apparatus had the form of large osmiophilic (argentophilic) rings or

anules. At the later period after afferent
nervation a marked reduction of Golgi apparatus
ements occurred. Mitochondria were also markedly
anged in the deafferentated liver; soon after
rgery they became round and swelled, while
ter 2-4 mo. they became fine-grained and
rkedly decreased in number. This apparently
dicates inhibition of the cellular metabolic
ocesses connected with the mitochondrial func-
ons.

097 DETERMINATION OF SULFOBROMOPHTHALEIN
STORAGE AND EXCRETORY RATE IN SMALL
IMALS. (E.) Klaassen, C. D. (U. Iowa, Iowa
ty) and G. L. Plaa. J. Appl. Physiol. 22(6):
51-1155, 1967.

moval of BSP from plasma by the liver involves
th excretion and storage. A method was devised
simultnaeous determination of relative storage
acity and transport max. in small laboratory
mals, and was compared with Wheeler's method,
ch is presently used in dogs and humans. With
eeler's method, 4 blood samples are taken during
ch infusion period to determine change in plasma
c. for that infusion rate and the corresponding
atic removal rate; when the change in plasma
c. is plotted against hepatic removal rate,
slope of the line is the relative storage
acity and the value of the hepatic removal rate
n change in plasma conc. is zero is the trans-
t max. The new method determined hepatic re-
al against change in plasma conc. differently;
nge in plasma conc. is derived from 4 blood
ples obtained during a 90-min. infusion period,
the transport max. is determined directly by
lysis of BSP in the bile during the same in-
ion period. Comparable values were obtained
dogs by the proposed method when compared to
eler's method, thus substantiating use of the
proposed method in small animals. This is in
eement with what would be expected if the pro-
ed method were validly determining relative
rage capacity and transport max. Using this
posed method, the following transport max.
ues (mg/min./kg) were obtained in anesthetized
mals: dog, 0.17; rabbit, 1.05; and rat, 0.97.
following relative storage capacity values
BSP/mg%/kg body wt.) were simultaneously ob-
ned: dog, 2.4; rabbit, 0.55; and rat, 0.47.

98 IN VITRO DEIODINATION OF ^{131}I ROSE
BENGAL BY RAT LIVER HOMOGENATES UNDER
FERENT METABOLIC CONDITIONS. (Ger.) Voss, C.
Greifswald, Germany), N. Hartmann, B. Wirthgen
H. Bergner. Acta Biol. Med. German. 18(4):
-456, 1967.

ups of white rats were fed 3 separate diets
periods of 8 and 14 days; the first group
a normal diet containing dried milk as a
rce of protein, the second had a protein-free
t and the third received protein in the form
gelatin. Stimulants of metabolism, triiodothy-
ine and dessicated thyroxine and an inhibitor, methylthiouracil were tried in conjunction with the diets to study the in vitro deiodination of ^{131}I-labeled rose bengal. At the end of the feeding period, the livers were excised; following washing and homogenization in buffer, protein was determined in part of the homogenate. Other portions (0.5 ml) of the homogenate were mixed with 30 or 46 µg of radioactive rose bengal (about 6-8 µc) and incubated for 18 hr. at 37°C. After incubation and precipitation of protein the preparation was subjected to paper chromatography. The radioactivity of the fractions was measured by a Geiger-Müller counter and the fractions identified by autoradiography. The homogenate of the normal liver (animals on normal milk diet) had 60% deiodination of rose bengal, the iodine being split off as free I_2. Triiodothyronine, desiccated thyroxine as well as methylthiouracil all repressed the liberation of I_2 from rose bengal. The gelatin diet also reduced the splitting of I_2 from the dye.

11099 HEPATIC SUPPRESSION OF SENSITIZATION TO ANTIGEN ABSORBED INTO THE PORTAL SYSTEM. (E.) Cantor, H. M. (New York U. Sch. Med., N. Y.) and A. E. Dumont. Nature (London) 215(5102):744-745, 1967.

Healthy adult mongrel dogs (20) were divided into 4 equal groups. In Group 1, conc. of antidinitrophenol antibody were measured in blood samples collected from 5 dogs that had no known exposure to 1-chloro-2,4-dinitrobenzene. In Group 2, a soln. of 8 mg of the latter agent in 1 ml of olive oil was inj. s.c. into each of 5 dogs in quantities of 400 µg on the first day, and 200 µg on days 5, 8, 11, and 15; on the twenty-sixth day after the first inj., blood samples were collected and levels of antidinitrophenol antibody were determined. In Group 3 the dinitrophenol dissolved in corn oil (20 mg/ml) was mixed with meat and fed to 5 dogs; on the thirty-fourth day, dinitrophenol was inj. s.c. according to the same schedule followed in Group 2; 26 days after the initial s.c. inj., blood samples were collected and determinations of antibody were made. In Group 4, complete portacaval transposition was done on each of 5 dogs; on the seventieth postoperative day, p.o. feedings of dinitrophenol were begun and thereafter the regimen was identical to that carried out in animals in Group 3. Serum from animals of Group 1 contained no measureable antibody; titers of antibody in Group 2 animals ranged from 1:64 to 1:512. In contrast, sera of 2 of the animals in Group 3 contained no measurable amounts of antibody, in 2 the titers were 1:4, and in 1 the titer was 1:16. Sera of dogs in Group 4 contained antibody in practically identical amounts to sera of dogs in Group 2, ranging from 1:64 to 1:256. These results indicate that repeated p.o. feeding of 1-chloro-2,4-dinitrobenzene to adult dogs before s.c. inj. suppresses the formation of specific circulating antibodies and that diversion of portal flow from the liver abolishes this effect.

11100 CHANGES IN THE ACTIVITY OF ARGINASE IN LIVER, SERUM, AND RINSING FLUID FROM THE PERITONEAL CAVITY AFTER *IN VIVO* AUTOLYSIS OF A LIVER LOBE IN THE RAT. (Ger.) Blech, W. (Martin Luther U., Halle/Saale, Germany). *Z. Ges. Exp. Med.* 144(2):134-144, 1967.

The left liver lobe (about 33% of the total liver) of the rat was ligated at the base and each rat received 5 ml of 0.9% NaCl soln. s.c. Neither peritonitis nor ascites occurred. The ligated lobe was left *in situ*. Arginase activity was determined in the blood serum of experimental and control animals at 6, 12, 24, and 48 hr.; the intact liver and the ligated lobes were removed, separately homogenized, and the enzyme activity of the homogenates measured. In a second series of experimental and control rats, blood was obtained from the tail vein at 6, 12, 18, 24, 36, 48 and 96 hr. Also, 2.0 ml of 0.9% NaCl was inj. i.p. after which the fluid from the peritoneal cavity was drained by means of a cannula and the arginase conc. determined. Enzyme analysis was done by paper chromatography. Arginase activity decreased rapidly during *in vivo* autolysis in the ligated lobe of the rat liver; 48 hr. after ligation the arginase in this lobe was only 40% of that in the intact liver lobes. Arginase activity was present in the peritoneal saline rinse rising to a max. 12 hr. after ligation. Arginase appeared in the serum almost at the same time. In normal animals and after sham operation, no arginase could be detected in the serum or in the peritoneal fluid.

11101 POTASSIUM, SODIUM, AND WATER CONTENT OF LIVER CELLS AND ERYTHROCYTES INCUBATED IN ISOTONIC AND HYPERTONIC SOLUTIONS. (Ger.) Burck, H. C. (U. Tubingen, Germany). *Z. Ges. Exp. Med.* 144(2):93-104, 1967.

RBC and liver slices of the rat were analyzed for K and Na by flame photometry, and the H_2O content determined after incubation in isotonic (0.3 osmoles) and in hypertonic (0.45 osmoles) soln. for 7-360 min. Normal liver cells react like normal human RBC in that Na, K and H_2O content are related in direct regression. Alterations in conc. of ions reflect different degrees of hydration. During incubation cells gain more Na than they lose K resulting in a 50% net gain in total base (Na) caused by a breakdown of the Donnan membrane equilibrium in resp. to this ion. This occurs in both media and then remains constant at this level. The Na:K quotient rises from 0.33 to 3.4 (0.45 osmolar soln.). More K is released from the cell as intracellular Na increases. The cells in the isosmotic medium remain isosmotic and those in the hypertonic medium are hypertonic, although intracellular H_2O has increased in the cells in the hypertonic soln.

11102 EFFECT OF PROGRESSIVE STARVATION ON RAT LIVER ENZYME ACTIVITIES. (E.) Freedland, R. A. (U. California, Davis). *J. Nutr.* 91(4):489-495, 1967.

During progressive starvation in rats, the mos stable enzymes were those associated with gluc ogenesis, glycolysis and the citric acid cycle The activities of enzymes thought to be indire involved in lipogenesis were the least stable. The following was observed in young rats: tot liver protein, liver glycogen phosphoglucomuta fructose diphosphatase, aldolase, succinic dehydrogenase and fumarase decreased in activity after 1 day of starvation, then remained const the next 3 days. On days 1 and 4 of starvatio a decrease was noted with soluble liver protei phosphohexoseisomerase, glyceraldehyde-3-phosp dehydrogenase, LDH, α-glycerophosphate dehydro enase, malic enzyme, isocitric dehydrogenase a malic dehydrogenase. A decrease in the activi of phosphorylase, glucose-6-phosphate dehydrog 6-phosphogluconate dehydrogenase and the pento phosphate-metabolizing enzymes was observed on days 1, 2 and 4. Glucose-6-phosphate and ur diphosphate glucose dehydrogenase activities r mained constant until a decrease on day 4. Ge erally, the trends were similar with older rat with the following exceptions: a sharp decrea on day 1 in the uridine diphosphate glucose de hydrogenase, a greater decrease in glucose-6-phosphatase and lactate dehydrogenase activity and a greater resistance to decreased activity aldolase, α-glycerophosphate dehydrogenase, is citric dehydrogenase and glucose-6-phosphate d hydrogenase.

11103 CIRCADIAN RHYTHMS OF LIVER ENZYMES A THEIR RELATIONSHIP TO ENZYME INDUCTI (E.) Civen, M. (VA Hosp., Long Beach, Calif.) R. Ulrich, B. M. Trimmer and C. B. Brown. *Sci* 157(3796):1563-1564, 1967.

Male Sprague-Dawley rats were used to assess circadian changes in 2 liver enzymes, tyrosine α-ketoglutarate transaminase and phenyl-alanir pyruvate transaminase; the former is known to inducible by glucocorticoids and glucagon, whi activity of the latter enzyme changes only sli after repeated inj. of glucocorticoids. Tyros α-ketoglutarate transaminase showed circadian rhythmicity in the intact rat; it underwent a change, with minimum activity at 11 a.m. and m activity at 9 p.m.; plasma corticosterone rose from its minimum level at 6 a.m., to its max. 6 p.m., with an increase of 1870%; the peak activity occurred 3 hr. after the max. corticosterone level. This rhythmicity was only slightly altered after adrenalectomy, indicati that adrenal hormones do not play a major role in the metabolic control of the activity of ty rosine α-ketoglutarate transaminase. On the other hand, phenylalaninepyruvate transaminase which is not inducible over the same period, c not show circadian variation. These results s gest that the sensitivity of an enzyme's regul ing system to inducing agents may be related t the inherent circadian rhythm of the enzyme.

11104 THE EFFECT OF SOME APORPHINE ALKALOI ON BILE SECRETION IN RATS. (Pol.)

kowski, B. (Inst. Pharm., Warsaw), A.
perak-Neciażek, K. Obojska and Z. Szmal. Diss.
rm. (Krakow) 18(5):455-465, 1966.

otal of 141 Wistar rats (160-250 g) were
ided into 6 groups and the effect of glaucine,
corydine, magnofluorine and boldine on secre-
n of bile, its dry residue, and chromatographic
tern was studied. Bile was collected through
atheter inserted into the bile duct 0.8-1.0 cm
n its duodenal opening and connected to a
ibrated pipette. Determinations were made at
r. intervals. The first hr. was used as a
trol after which the compounds were inj. into
duodenum in a vol. of 1 ml/100 g body wt.
up 1 (11 rats) served as control, Group 2 (10)
eived 200 mg/kg of dehydrocholic acid and
ved as standard, Group 3 (35) was given 200,
nd 20 mg/kg doses of glaucine hydrochloride
the duodenum and 5 mg/kg i.v. Group 4 (35)
eived 200, 50 and 5 mg/kg of isocoridine,
up 5 (20) 50 and 5 mg/kg of magnofluorine per-
rate and Group 6 (30) 20 and 5 mg/kg of
line. Glaucine in 50 mg/kg dose and isocoridine
0 and 5 mg/kg dose increased bile secretion
were both toxic in the 200 mg/kg dose causing
h of 40-50% of animals after 2-3 hr. Magno-
rine had no effect on vol. or quality of
eted bile. Boldine in 20 mg/kg dose caused
all decrease of bile vol. after 2 and 3 hr.
matographic analysis showed a decrease of
acids after glaucine and isocoridine which,
a simultaneous decrease of dry bile residue
increased vol. of secreted bile points to a
eretic action of these compounds. Boldine
eased the amount of dry residue and chromatog-
y showed an increase of bile acids and phos-
ipids with this compound indicating that it
ulates bile synthesis.

5 FUNCTION OF THE LIVER CELLS IN THE SHORT-TERM AND THE LONG-TERM CULTURES. I.
MIN PRODUCTION OF THE LIVER CELLS IN VITRO.
Namba, M. (Okayama U. Med. Sch., Japan).
Med. Okayama 20(6):251-259, 1966.

min production of cultured liver cells (5
erent cell strains) was studied by immunolog-
methods, especially immunofluorescence and
complement fixation test. Albumin production
detected in the strain RLN-10 liver cells
blished from the liver tissues of a Donryu
this confirmed that the cultured liver cells
tained the function of producing albumin, and
e cells originated from parenchymal liver
s. Two hepatoma strains also showed produc-
of albumin, but the extent of its production
less than that of strain RLN-10; this in-
ted that hepatoma cells maintain some functions
ormal liver cells. In short-term culture,
r cells did not show albumin production after
., but after 3 mo. slight albumin production
demonstrable. It is thought that cultured
r cells adapt themselves to the new culture
itions and gradually begin to display some
he functions of the liver cell. A certain time period may be necessary before cultured cells adapt to the in vitro environment. The proliferation rate of strain RLN-10 liver cells was approx. 3-5 fold in 7 days, using a medium consisting of 20% bovine serum, 0.4% lactalbumin hydrolyzate and buffered saline; the chromosome distribution was near the triploidy region, but the relationship between the albumin production and the chromosome number could not be ascertained.

11106 THE FINE STRUCTURE OF RAT LIVER CELLS IN SUSPENSION. (E.) Carr, K. E. (U. Glasgow, Scotland), J. P. Arbuthnott, P. G. Toner and C. G. Gemmell. Z. Zellforsch. 79(2): 265-271, 1967.

The method of Jacob and Bhargava was evaluated for its merit in obtaining high yields of parenchymal cells from perfused rat liver by comparison with a modification characterized by the use of less mechanical pressure. Material for fine structure study by electron microscopy was embedded in epoxy resin in an attempt to avoid the polymerization damage which can occur with methacrylate embedding. Both methods gave recognizable hepatic parenchymal cells under the light microscope although certain cell debris, including nuclei, was seen. The fine structure of perfused liver slices appeared to be relatively normal. Neither the mitochrondria nor granular endoplasmic reticulum was distorted in the majority of instances and cell membranes were intact. In contrast, the fine structure of hepatic cell suspensions prepared by the method of Jacob and Bhargava or by its modification was markedly distorted. Discontinuities of the cell membrane were present in all samples, the faults ranging from small gaps to extensive ruptures. The membrane itself appeared thinner and less regular than in tissue slices and the type of damage observed in the cell membranes could possibly be a cause of increased permeability. The limitations of cell suspensions as models of biochemical function are discussed.

11107 ENZYMES OF FRUCTOSE METABOLISM ACTIVITY AND DISTRIBUTION IN THE RAT LIVER. (Ger.) Heinz, F. (Munich Techn. Inst., Germany) and W. Lamprecht. Hoppe Seyler Z. Physiol. Chem. 348(7):855-863, 1967.

In the rat liver homogenized in the cold and centrifuged for 20 min. at 30,000 revolutions/min. at 5°C, the clear supernatant was used for the determination of cellular enzymes involved in fructose metabolism. Mitochondria, microsomes and nuclei were separated by differential centrifugation and the enzyme content of each entity was established with resp. to fructose metabolism. New and simple methods for determination of triokinase and aldehyde dehydrogenase are described. Ketohexokinase, ketose-1-phosphate aldolase, triokinase and hexose diphosphatase were found only in the cytoplasm. Aldehyde dehydrogenase, D-glycerate kinase and the sorbitol dehydrogenases were present in both the cytoplasm and mitochondria. A physiological reduction of

D-glyceraldehyde to glycerol followed by phosphorylation to L-glycerol-3-phosphate seems improbable from kinetic measurements. Alcohol dehydrogenase and glycerol kinase were confined to the cytoplasm. D-glyceraldehyde may be metabolized in or on the surface of the mitochondria. A comparison of the activities of hexokinase and ketohexokinase show that, under optimal conditions, more fructose than glucose can be metabolized in the liver.

11108 PROTEIN SYNTHESIS IN VIVO IN THE PANCREAS AND LIVER OF THE RAT UNDER NORMAL CONDITIONS AND DURING LEUCINE AND THREONINE DEFICIENCY AND DURING RECOVERY FROM THE DEFICIENCY. (Fr.) Vandermeers, A. (Free U. Brussels), M. C. Vandermeers-Piret and J. Christophe. Bull. Soc. Chim. Biol. (Paris) 49(7):759-778, 1967.

Male white rats were divided into 3 groups; the first group received a complete diet; the second a diet based on gluten and deficient in lysine and threonine; the animals were sacrificed after 23 days. The third group received a deficient diet for 20 days then casein-DL-methionine for 3 days before sacrifice. The animals each received i.p. 3.5 μc of ^{14}C L-leucine and were killed 5, 10, 20, 30 and 60 min. later; blood from each group of animals was pooled, centrifuged, and the radioactivity of the plasma leucine and other radioactive compounds (proteins) determined. Pancreatic and liver tissues were homogenized and radioactive compounds analyzed by radiochromatography. The labeling of pancreatic and liver proteins was compared to the specific radioactivity of free leucine in the tissues and in the plasma. Av. rate constants for protein biosynthesis and protein turnover were calculated from the data collected before degradation and/or exportation of newly-synthesized proteins. In 200 g control rats, the turnover time of pancreatic proteins was 34 hr.; a smaller value (24 hr.) was calculated for liver proteins; this value was apparently shortened by a dilution factor, mainly of dietary origin. Rats of identical age but of only 100 g wt. after 3 wk. of lysine and threonine deficiency synthesized 101% more pancreatic proteins and 41% more liver proteins on a tissue wet wt. basis. The low protein content of these tissues indicated an accelerated transfer and/or degradation rather than an inadequate synthesis. Rats having recovered from amino and deficiency during a period of 3 days increased pancreatic protein synthesis still further and the turnover time was reduced to 8 hr. The liver seemed less active, but the heterogeneity of the free leucine pool was a complicating factor.

11109 HISTOCHEMISTRY OF THE LIVER. BIOCHEMICAL AND ELECTRON MICROSCOPE COMPARISONS. PART 2. (Fr.)(Rev.) Corcos, V. (St. Antoine Hosp., Paris), A. Lageron, R. Wegmann and J. Caroli. Rev. Int. Hepat. 17(4):267-365, 1967.

56 THE DETERMINATION OF MAXIMUM BILIRUBIN
BINDING CAPACITY OF HUMAN ALBUMIN AND
UM BY A CALCIUM CARBONATE ADSORPTION TECHNIQUE.
) Rutkowski, R. B. (Walter Reed Army Med.
., Washington, D. C.). Clin. Chim. Acta
1):31-38, 1967.

ethod was devised to study the feasibility of
arating unbound bilirubin from albumin-bound
irubin by bath calcium carbonate adsorption,
ed upon previous observations that suspensions
calcium carbonate completely adsorbed unbound
irubin from soln. but had little adsorptive
action for albumin and other serum proteins.
procedure was used to study bilirubin binding
uman albumin and serum as well as effects of
ral serum and plasma fractions on the binding
acity of human albumin. Serum gave variable
consistently higher bilirubin albumin molecular
ding ratios than did purified albumin when
ed in dilute soln. In more conc. soln., serum
ding capacity decreased dramatically. Results
ined in studies testing serum and plasma
ein fractions for their effect of bilirubin
ding by albumin suggested that an interaction
lbumin with a high-density lipoprotein
uenced binding capacity. This study demon-
ted that calcium carbonate selectively adsorbs
und bilirubin from bilirubin-albumin soln.

7 AN IMPROVED PERFUSION TECHNIC FOR
RECOVERING ADULT SCHISTOSOMES FROM
RATORY ANIMALS. (E.) Duvall, R. H. (NIH,
esda, Md.) and W. B. DeWitt. Amer. J. Trop.
16(4):483-486, 1967.

chnic for recovering adult schistosomes from
rimentally-infected animals is described,
ng use of an automatic pipetting machine
h serves as a perfusion pump. The method
ists in admin. i.p. a combined inj. of pento-
ital sodium and heparin to produce a shift of
worms from the mesenteric veins to the liver,
to prevent clotting while they are perfused
ctly into conical sedimentation glasses for
ection and counting. Complete shifting of
worms greatly facilitates their recovery, and
overdose of anesthetic causes death of the
al within 3-5 min. The method described
ies to recovery of womrs from mice, but can
dapted with minor changes for use on other
ratory animals. Better than 98% efficiency
ecovery of worms is obtained. The method is
ly efficient in recovering very small worms
in detecting unpaired females. The data also
cate that the perfusion technic is as efficient
recovery of worms from mice with chronic
ctions as it is from mice recently infected.
typical experiment involving 50 mice infected
3 wk., a total of 1224 worms were recovered,
. of 24.5/mouse. Only 4 additional worms
recovered from the perfused mice by meticulous
ination of the liver, lungs and intestinal
vessels. It is emphasized that the method
apid and simple.

11158 ARTIFACTUAL LOWERING OF THE TOTAL BILIRUBIN VALUE. (E.) Baer, D. M. (Providence Hosp., Portland, Ore.) and D. C. Wood. Clin. Chim. Acta 17(1):1-3, 1967.

Occasionally, jaundiced patients are encountered in whom the total bilirubin is apparently less than the direct reacting fraction. Apparently, dyphylline and (presumably) caffeine react with the bilirubin to inhibit the diazo reaction. Although the reaction is prevented to some degree by the 3-fold dilution of serum and diazo in the total procedure as compared to the direct procedure, this inhibition is insignificant when compared to that produced by dyphylline. Increasing the quantity of diazo reagent causes elevations of the direct-reacting fractions, but not the total. Using serum from a patient with nutritional cirrhosis, a modification of the Michaelsson-Jendrassik-Grof procedure was devised to eliminate this artifact; dyphylline inhibition was overcome by allowing the diazo to react for 2 min. before addition of dyphylline in the total bilirubin reaction procedure.

11159 POSTERIOR PITUITARY EXTRACT IN THE TREATMENT OF DIGESTIVE HEMORRHAGE. (Fr.) Bories-Azeau, A. (St. Eloi Hosp., Montpellier, France), R. Colin and J. Dossa. Arch. Mal. Appar. Dig. 56(5):429-434, 1967.

Posterior pituitary extract (30-40 U in 200-250 ml of isotonic saline) was i.v. infused over a 20-min. period after blood transfusion restoring blood vol. in 28 cases of hemorrhage. Of these 28 cases, 16 resulted from portal hypertension, 5 from ulcers, 4 from aspirin or cortisone, and 3 from unknown causes; all required immediate treatment. Hemostasis was obtained during the first hemorrhage with the first inj. of the extract in 22 of 29 cases (75%); of these 22 patients, 17 recovered without further hemorrhage, 11 received medical treatment with only 2 deaths, and 6 underwent surgery with 1 fatality. Among 5 patients with relapses, 1 recovered and 4 died. Infusion of posterior pituitary extract had no effect on the primary hemorrhage in 6 subjects, 2 dying after emergency portacaval anastomoses, 2 dying with inoperable portal hypertension, and 2 recovering after intervention for gastric ulcer. Posterior pituitary extract reduced the portal pressure and liver blood flow.

FACTORS INFLUENCING THE TEARING STRENGTH OF GASTROTOMIES AND ENTEROTOMIES. EXPERIMENTAL INVESTIGATIONS WITH REFERENCE TO DEHISCENCE OF SUTURES IN CANCER SURGERY. (Ger.) Priesching, A. (U. Clin. Vienna). Klin. Med. (Wien) 22(5):201-232, 1967 and 22(6):241-260, 1967.

Mechanical factors such as the placement of surgical clamps during operation and the optimal distance between sutures were investigated. The effect of ligation of blood vessels, such as is necessary for interposition of intestinal segments, upon total blood flow and anastomosis strength was measured. The intestinal application of Periston-N (polyvinylpyrrolidone) or a soln. of electrolytes increased the tearing strength of intestinal segments with ligated blood vessels. Trenimon (triethyleneiminobenzoquinone) reduced the mechanical strength of anastomoses not only in a general dose-related manner but also in relation to other factors, e.g., the extent of the incision; wound healing was affected by doses which were not injurious to the animal as a whole (as body wt.). Cyclophosphamide affected general conditions of the animals but not wound healing. An uncorrected acute hyporolemia reduced resistance of the anastomoses. Other factors which underwent extensive investigation were: extent of operation (splenectomy, pancreatosplenectomy, liver resection) in correlation to wt. of the adrenal glands, the neutral effect of Trasylol following pancreatectomy, lack of value of adhesions as an indication of wound healing, summation of multiple factors occurring during wound healing. The effect of these factors and others were measured in large groups of animals and statistically evaluated.

11161 EFFECT OF EPINEPHRINE ON CELIAC AND SUPERIOR MESENTERIC ANGIOGRAPHY. (E.) Boijsen, E. (Univ. Hosp., Lund, Sweden) and H. Redman. Invest. Radiol. 2(3):184-199, 1967.

The inj. of small doses of epinephrine into the celiac and superior mesenteric arteries prior to angiography has shown promise in improving detection of lesions of upper abdominal organs. On 65 unselected patients, the practicability of epinephrine in the diagnosis of various lesions of 2 vascular beds and the physiologic changes involved was studied. The usual angiographic procedures were performed, using 1 or 2 catheters, and evaluation was made of changes in arterial detail, transit time of contrast material, capillary accumulation, venous opacification and diagnostic efficacy. A marked difference was seen in the effect of epinephrine on the various splanchnic arteries. An actual decrease in transit time of the contrast material was seen in bowel arteries. Pancreatic vessels were not constricted except in the presence of chronic pancreatitis while duodenal arteries showed increased filling following drug admin., capillary accumulation was generally reduced except in the duodenum. Veins were not seen as well except in the superior mesenteric distribution. Primary and secondary tumors were better seen after epinephrine if they were vascular and if the contrast material reached the vascular bed of the tumor. Carcinomas of the stomach were not detected as well because of marked constriction of the gastric vessels. Inflammatory lesions showed increased constriction after the drug; duodenal lesions were an exception. The drug did not affect collateral vessels. Complications from epinephrine admin. were not evident in this study but toxic effects should be kept in mind. This technic is suggested for physiologic investigations.

11162 THERAPY OF PERITONITIS AND WOUND INFECTION. (E.) Prohaska, J. V. (U. Chicago, Ill.) and R. Kramar. Pacif. Med. Surg 75(4):251-257, 1967.

In 25 patients with toxic megacolon, 10 had perforation and peritonitis, and 15 had neithe of these complications. Of those with toxic megacolon and peritonitis, 4 were treated with peritoneal lavage with normal saline soln. (co taining 1 g of oxytetracycline) followed by continuous i.v. infusion of 1 g oxytetracyclin hr. for 3 days. There was 1 death, giving a 25% mortality rate. Among the 6 patients with toxic megacolon and peritonitis not treated wi oxytetracycline, there were 5 deaths, giving a mortality rate of 83%. Another group of 15 patients suffering with ulcerative colitis or regional enterocolitis developed peritonitis f various sources; this group suffered generaliz peritonitis complicating the inflammatory dise of the large or small intestine. Together wit those with toxic megacolon and peritonitis, th made a total group of 25 with peritonitis. Th were 10 (40%) not treated with oxytetracycline with 5 deaths (50%), but among 15 (60%) treate with oxytetracycline, there were only 2 deaths (13%), giving a survival rate of 87%. In a to group of 73 patients with ulcerative colitis, ileocolitis or regional enteritis, whose cours was complicated by toxic megacolon, with or without colon perforation or by enterocutaneou fistulae, the incidence of wound infection was 20%, being 32% in the untreated group and 6% i the group that received oxytetracycline therap It is concluded that oxytetracycline-saline wa of the contaminated peritoneal cavity signific reduces the mortality rate from peritonitis an sepsis.

11163 A NEGLECTED ROENTGEN DIAGNOSTIC FEAT OF RUPTURED ANEURYSMS OF THE ABDOMIN AORTA. (E.) Nevin, I. N. (St. Mary's Hosp., Rhinelander, Wis.). J. Lancet 87(7):259-261, 1967.

Review of anteroposterior films of the abdomen of 5 consecutive, verified cases of ruptured aneurysms of the abdominal aorta revealed a triangular-shaped soft-tissue density along th left side of the pelvic cavity. The medial border of this density ran diagonally from ab the inferior border of the sacroiliac joint to the ischial spine along the expected position the pelvic portion of the psoas muscle. The lateral border of the soft-tissue density con formed to the inner aspect of the iliac bone sometimes overlapped the bone itself. This density was slightly above the expected locat of the obturator internus muscle. The soft-tissue density is thought to represent the

nward extension of a retroperitoneal hematoma
m the ruptured aneurysm along the pelvic
tion of the psoas muscle. When there is
nical or radiological evidence of an aneurysm,
presence of this soft-tissue density may
rt the clinician to the probability of a
ture; this may be of more significance than
obliteration of the psoas muscle, which has
n known to occur in some abdominal aneurysms
hout rupture.

64 THE ROLE OF SPECIFIC BACTERIOPHAGE IN
THE CONTROL OF THE CARRIER STATE OF
GELLA FLEXNERI 6 BACILLI. (Pol.) Mulczyk, M.
st. Immunol., Wroclaw, Poland), S. Ślopek and
Marcinowska. *Przegl. Epidem.* 21(2):179-182,
7.

outbreak of dysentery caused by *Shigella*
xneri 6 in a children's home involving 14
ldren and 4 adults was treated with sulfonamides
antibiotics; symptoms disappeared, but the
ated patients remained carriers. Sporadic
ppearance of symptoms resisted therapy with
h doses of sulfguanidine, Chlortetracycline
tetracycline and chloramphenicol. Isolated
gella organisms were tested for sensitivity
12 strains of bacteriophages which are usually
d for typing of *S. flexneri* strains and were
nd to be sensitive to phage F 10. This phage
then grown on cultures of *S. flexneri* 6
ntained in broth and phage lysates of a 10^{10}
er were thus obtained. The bacteriophage was
en p.o. to carriers in a 2% soln. of bicarbonate
soda (5 ml to children, 15 ml to adults) 3
es daily, 1 hr. before meals, for 4 days. The
ol was examined 3 times in 3-4-day intervals
the presence of *Shigella* and treatment and
ol examinations were repeated twice at 2-wk.
ervals. In only 1 of the 18 patients was
flexneri, which was resistant to phage 10,
lated. Follow-up examinations of stools during
next 7 mo. remained negative. A yr. later a
outbreak of dysentery involving 34 newly-
itted children was treated in the same manner
excellent results. After the second admin.
the phage there were no carriers and stools
ained negative on repeated follow-up examina-
ns. The isolated *S. flexneri* strain contained
Resistance Transfer Factor. It is concluded
t since the resistance transfer factor is
ountered more and more frequently in strains
Shigella and *Salmonella*, chemotherapy will
ome more difficult. The use of specific
teriophages in the treatment of intestinal
ections and carrier states should be seriously
sidered.

GASTROINTESTINAL DISEASES

GENERAL

11214 SOME PHYSIOLOGICAL, BIOCHEMICAL, AND MORPHOLOGIC EFFECTS OF TRIS (p-AMINOPHENYL) CARBONIUM SALTS (TAC) ON *Schistosoma mansoni*. (E.) Bueding, E. (Johns Hopkins U., Baltimore, Md.), E. L. Schiller and J. G. Bourgeois. *Amer. J. Trop. Med.* 16(4):500-515, 1967.

Subcurative doses of the antischistosomal drug tris (p-aminophenyl) carbonium chloride were given to adult white or C3H mice infected with cercariae of *Schistosoma mansoni*. This agent produced 3 distinct changes in the parasite. A reduction of glycogen occurred in the cuticular tubercles of the males; this was followed by a flattening and subsequent disappearance of these structures. Alterations in the morphologic and functional properties of the female reproductive system occurred; it was detectable by an *intra vitam* staining method and led to abnormal egg formation. In contrast to these 2 changes, the effects on the female reproductive system were not specific for tris (p-aminophenyl) carbonium chloride, but were also observed after admin. of subcurative doses of other antischistosomal drugs. At a later stage, inhibition of acetylcholinesterase activity in the nervous system of the worm was produced, resulting in a paralysis of the adhesive organs. This coincided with the separation of the sexual pairs and a shift of the worms from the mesenteric vessels toward the liver. The drug-induced paralysis of the adhesive organs was reversed immediately on exposure of the worms to cholinergic-blocking agents *in vitro*.

11215 FAMILIAL POLYPOSIS ASSOCIATED WITH A NEW TYPE OF SOFT-TISSUE LESION (SKIN PIGMENTATION): REPORT OF THREE CASES AND A REVIEW OF THE LITERATURE. (E.) Weston, S. D. (Caledonian Hosp., Brooklyn, N. Y.) and M. Wiener. *Dis. Colon Rectum* 10(4):311-321, 1967.

Three brothers are described as all having the typical symptoms of Gardner's syndrome with the added feature of skin pigmentation limited to the torso. The first (age 24 yr.) presented with a history of irregular bowel action and occasional rectal bleeding. Examination showed that the entire rectal segment was involved with sessile and pedunculated polyps. Numerous sebaceous cysts were scattered over the body and pigmented spots were noted on the lower back. The accessible polyps were removed rectally and the remaining ones were fulgurated. Afterwards, a subtotal colectomy with ileoproctostomy was performed. The 16-yr.-old brother who was without complaints had marked rectal polyposis. Pigmentation was seen over the anterior and posterior chest and abdomen; Mandibular endosteal osteoma was also present. This patient was successfully treated in the same manner as the first. Examination of a third brother (age 17) who had a history of diarrhea, abdominal cramps and bloody stools also revealed sebaceous cysts, numerous pigmented spots on the chest, abdomen and back, osteomas of the parietal bone and discrete polyps of the rectum and rectosigmoid. Treatment was the same as th others. Examination of a sister was negative. The mother refused examination but the father had died of cancer of the rectum associated wit multiple polyposis. Four cousins were reported as having multiple polyposis and several uncles supposedly died of cancer of the bowels.

11216 UMBILICAL AND VENTRAL HERNIORRHAPHY: A REVIEW OF 1000 CASES. PART I. CHARACTERISTICS WHICH PREDICT SURGICAL RESULTS AND PREDISPOSING FACTORS. (E.) Musca, A. A. (Cleveland Metropol. Gen. Hosp., Ohio). *Int. Surg.* 48(2):169-179, 1967.

Of 1008 patients who underwent a total of 1108 umbilical and ventral herniorrhaphies, 75% were operated upon in an indigent clinic, whereas th rest were treated in a private clinic. Incisio hernias were most common (56%) and were general found in the lower abdomen and usually represen secondary complications of prior surgery. More patients with incisional hernia were treated at the private clinic, whereas more patients with umbilical hernia were treated at the indigent clinic; more umbilical hernias were observed in female patients. Both hernia types had a highe incidence in female patients who were Caucasian and who were also obese. There was associated lung disease in 8.9% of the patients and urinar or gastrointestinal disease in 3.4%. Disorders of the supporting tissues occurred in over 50% of the evaluated patients and included hemorrho (17.2%), varicose veins (14.1%), other hernias (11.4%), cystocele and rectocele (13.2%) and diverticulosis (6.5%). Emergency procedures we conducted with greater frequency at the indigen clinic as compared with the private clinic (23.0% to 8.1%). There was no correlation betw the duration of symptoms and intestinal viabili however, the mortality rate was correlated with intestinal viability (22.2% rate for gangrenous intestines and 10.5% rate for incarcerated, but unstrangulated intestines). The mortality rate was also in direct proportion in those patients who were older and also in those with associate systemic disease. Patients with Laennec's cirr sis showed a death rate of 20%. In patients of more than 200 pounds, the incidence of lung emb was 5% and the incidence of thrombophlebitis wa 10%.

11217 IMPAIRED LYMPHOCYTE TRANSFORMATION AN DELAYED HYPERSENSITIVITY IN SJÖGREN'S SYNDROME. (E.) Leventhal, B. G. (NCI, Bethesd Md.), D. S. Waldorf and N. Talal. *J. Clin. Inv* 46(8):1338-1345, 1967.

In vitro lymphocyte transformation in response phytohemagglutinin and streptolysin 0 and *in vi* skin sensitization to 2,4-dinitrochlorobenzene

s studied in 33 patients (2 men, 31 women; 30-
yr. old, with a mean of 55 yr.) with Sjögren's
ndrome (who had symptoms for 1-21 yr.), in 17
tients with classical rheumatoid arthritis (4
n, 13 women; 2-60 yr. old) and in 20 normal
ntrols (2 men, 18 women; 25-68 yr. old). Of
ose with Sjögren's syndrome, 13 had the sicca
ndrome alone, 12 had the sicca syndrome and
eumatoid arthritis, 1 had sicca syndrome with
mphoma and 7 had the sicca syndrome with
eudolymphoma. 2,4-Dinitrochlorobenzene was
lied as 2000 μg in 0.1 ml acetone to an area
the upper arm skin. Both the in vivo and
vitro responses were significantly impaired
the Sjögren patients as compared to controls.
s lack of mitogenic agents is probably due to
intrinsic defect in the lymphocytes rather than
a serum factor. Abnormalities were less marked
those patients whose disease was localized to
parotid and lacrimal glands than in those
h generalized disease, i.e., with complicating
udolymphoma or rheumatoid arthritis. Delayed
ersensitivity was found in 16 of 17 normals,
of 15 (67%) with rheumatoid arthritis and 8 of
with Sjögren's syndrome; the latter included
f 9 with sicca syndrome alone (55%), 1 of 9
%) with sicca syndrome and rheumatoid arthritis
2 of 5 (40%) with sicca syndrome and pseudo-
phoma.

18 EXPERIMENTAL CHOLERA IN THE RABBIT
INTESTINAL LOOP: FLUID ACCUMULATION
SODIUM PUMP INHIBITION. (E.) Leitch, G. J.
Chicago, Ill.), W. Burrows and L. C. Stolle.
Infect. Dis. 117(3):197-202, 1967.

lyzable and nondialyzable fractions Vibrio
lerae 569B whole cell lysate were inj. into
duodenal and lower ileal loops of adult rabbits.
both the duodenum and ileum, the material
able of eliciting an accumulation of fluid in
lumen was nondialyzable. When the loop
nsmural potential difference was measured by
lanting electrodes in the rabbits, it was
erved that the dialyzate was capable of reduc-
the potential across the lower ileum, but
hout overt evidence of fluid accumulation, and
the duodenum neither fluid accumulation nor a
uction in potential difference were produced.
vitro measurement of the short-circuit current,
nsmural potential difference and tissue re-
tance of toxin-treated loops indicated that
reduced potential difference with dialyzate
a consequence of a reduced active Na transport,
ce the short-circuit current was reduced while
tissue resistance remained unchanged. It is
cluded that the choleragenic material responsi-
for the overt fluid accumulation in this
el is not the same as the material responsible
Na pump inhibition, but the evidence presented
not exclude a role of the latter in the
duction of cholera stool in man.

9 ACTIVE SODIUM TRANSPORT ACROSS RABBIT
ILEUM IN EXPERIMENTAL CHOLERA INDUCED
BY CHOLERAGEN. (E.) Norris, H. T. (Harvard Med.
Sch., Boston, Mass.), S. G. Schultz, P. F. Curran
and R. A. Finkelstein. J. Infect. Dis. 117(3):
193-196, 1967.

The effect of choleragen (a moiety isolated from Cholera vibrio) on Na ion transport across short-circuited segments of adult (New Zealand white) rabbit ileal loops was studied; short-circuiting was accomplished by bathing both surfaces of the isolated tissue with soln. of identical composition and, at the same time, passing sufficient current through the tissue to abolish the spontaneous transmural electrical potential difference. Under these conditions the electrochemical potential for Na in the mucosal soln. is equal to that in the serosal soln. so that net transport of Na from 1 soln. to the other cannot be the result of passive ionic diffusion. A total of 40 μg of choleragen in a total vol. of 1 ml was instilled into the lumen of 1 loop and 1 ml of sterile physiologic saline was instilled into the adjacent loop. No difference in the rate of active Na transport could be demonstrated between in vitro segments of choleraic and control tissues. Histologic examination demonstrated no epithelial discontinuity, but only congestion of submucosal and villous vessels, discharge of mucus and dilatation of the central lacteal.

11220 GEOGRAPHICAL DISTRIBUTION OF GASTRO-INTESTINAL CANCERS IN INDIA WITH SPECIAL REFERENCE TO CAUSATION. (E.) Malhotra, S. L. (Western Railway, Bombay, India). Gut 8(4):361-372, 1967.

An analysis of 470 cases of gastrointestinal cancers seen among the railway populations in various parts of India over the 5-yr. period 1960-1964 is presented; the data given are representative of the entire country, except the extreme eastern regions: Assam and parts of North Bengal. Sex distribution revealed 363 (77.2%) of the cancers were in males and 107 (22.8%) were in females. A total of 183 (39%) were cancers of the buccal cavity; this location for cancer was 4-fold more prevalent among men, and found its peak incidence among those aged 35-55 yr.; it was relatively less common in the south than in the north and east. Cancer of the esophagus accounted for 53 (11%) of 470; it was 7-fold more common among men, and constituted 55% of all cancers in the west and south of India. Cancer of the stomach constituted 18% (83 of 470) of all gastrointestinal cancers in this study; it was 4-fold more common in the south of India; the male:female ratio was 7:1 for the series as a whole, but in south India it was 20.1; it was most prominent in the 35-55-yr.-old-age group in the south, compared to 45-55 yr. old group in the north. There were 26 cases of hepatoma and 12 carcinomas of the gallbladder, constituting 38 (8%) of 470 cancers; it was 12-fold more common in the north than in the south; cancer of the liver was 1.5 times more common in males, and cancer of the gallbladder was 3 times more common in females. There were no significant geographical differences found for cancer of the rectum and colon. Eight cases of pancreatic cancer were recorded, being most common in south India. The geographical distribution of oropharyngeal cancers confirmed the association with betel chewing, but it is suggested that the irritation from the highly alkaline lime, and not the tobacco leaf, on the betal nut in the chewing quid, predisposes towards malignant changes in the buccal mucosa. The association of higher gastric cancer rates with lower hepatoma rates in 1 area of the country, and the reverse in another area, suggests that in the development of these neoplasms there may be common etiological factors, most of which are dietary. The pattern of diet and eating influences flow rates of bile, and the possible role of flow rates of bile in the pathogenesis of gastric carcinoma, on the one hand, and hepatoma and cancer of the gallbladder on the other, is considered. Geographical differences in the incidence rates of cancer of the colon appear to be related to dietary factors. A hypothesis is presented that malignant disease involving mucous membranes may be due to chronic interaction of an abnormal alkaline milieu on the intracellular mucus of the mucous cells of epithelium.

11221 PATHOMECHANISM OF COLI DYSPEPSIA. (Ger.) Kühn, B. (Karl Marx U., Leipzig, Germany), W. Raue and U. Willnow. Zbl. Bakt. [Naturwiss.] 203(2):172-176, 1967.

Of 28 infants who died of multiple infectious diseases, 24 had coli dyspepsia listed among the other often-related conditions diagnosed. Bacterial inocula from the small and large intestines, mesenteric lymph nodes, liver, and spleen was obtained. Histological investigations of the small and large intestines disclosed abnormal situations in every case. In most cases the Grünhagen subepithelial spaces were widened; more or less strong lymphocyte or plasma cell infiltration with occasional eosinophils in the mucosa and sloughing of the epithelial and goblet cells were evident. In a few cases spotty necrosis of the mucosa and bacterial colonies mixed with mucus and dislodged epithelial cells were seen. The submucosa regularly showed a slight edematous infiltrate containing a few round cells. Lymphatic tissue was strongly activated. Fluorescent microscopy revealed Escherichia coli (0111:B4) in 13 cases. The bacteria were well-differentiated with a yellow-green fluorescence of the capsules; in all 13 cases these bacteria were evident only in the intestine and in the intestinal contents. In contrast to the fluorescent method bacteriological proof of the strain of the organism occurred in only 8 instead of 13 cases.

11222 SERUM ANTIBODY RESPONSES TO INTESTINAL IMPLANTATION OF ANTIGENS IN RATS. (E.) Copper, G. N. (U. Melbourne, Australia) and J. C. Thonard. J. Path. Bact. 93(1):213-221, 1967.

Male albino rats were prepared with isolated intestinal loops by ligating 2 points approx. 4 cm apart at the ileojejunal region in such a manner that at least 1 Peyer's patch was include in the isolated portion of intestine. Control and operated animals received 0.2 ml of Shigella dysenteriae type-II suspension, containing 1 x 1 organisms s.c. The antibody response was simila in both groups of animals, showing that neither the stress of the operation nor recovery from it affected the capacity of animals to respond to this primary antigenic stimulus. Operated animals were given graded doses of antigen (rang from 10^5 to 10^9 organisms given in 0.1 ml vol.) by the i.p. and intraloop routes, and also grade doses of Shigella dysenteriae II endotoxin which ranged from 0.005-5 µg in 0.1 ml vol. No signif cant difference between the 2 routes of admin. were detected when the antigen dose was = to or greater than 10^7 organisms, but the i.p. route was more effective than the intraloop route when smaller doses were used. The primary serum antibody responses to graded doses of the bacter flagella antigen extracted from Salmonella enteritidis were compared; the antigen was given i.v. or in the isolated intestinal loop. The i.v. route seemed more effective when doses of 0.1 and 0.01 µg were used; with lower doses the results suggested that the intestinal route evok a more prolonged serum antibody response. Group of rats were also given doses of S. dysenteriae II endotoxin and S. enteritidis flagella intrajejunally and by the isolated intestinal loop; whereas the intrajejunal route was more effecti in producing a serum antibody response when endotoxin was used as antigen, the reverse prevailed with flagella, where even a dose of 0.1 µg elicited only minimal antibody titers. It is concluded that the isolated intestinal loop can have antigens inj. into it as a means of studyi the immunological reactivity of animals to anti in the intestine, and that animals produce seru antibody to titers similar to those elicited by parenteral inj. of several bacterial antigens.

11223 IMMUNOLOGICAL REACTIVITY ASSOCIATED W ANTIGENS IN THE INTESTINAL TRACT OF RATS. (E.) Cooper, G. N. (U. Melbourne, Austr ia), W. J. Halliday and J. C. Thonard. J. Path Bact. 93(1):223-233, 1967.

Shigella dysenteriae II endotoxin was labeled b incubation at 37°C with ^{51}Cr, and rats were giv 0.1 ml of a 20 µg/ml saline soln. of this by me of an intestinal loop. Salmonella adelaide flagellar material was labeled with ^{125}I, and rats were given 5 µg of this material in 0.1 ml of saline. The relative number of plaque-formi cells in spleen, mesenteric lymph nodes and Peyer's patches was assessed in rats given inj. of S. dysenteriae antigen. The bulk of the ^{51}Cr-labeled endotoxin remained in the isolated intestinal loop for a considerable period of ti after inj.; a small, but significant, amount of radioactivity was absorbed from the loop; most of this localized in the liver, although betwee

-10% was detected in other organs, particularly e spleen, thymus, kidneys and adrenals. Small nounts of radioactively labeled flagella or dotoxin accumulated in lymphoid tissue other an that associated with the intestinal loops, d may provide sufficient antigenic stimulus for generalized reticuloendothelial response. This s supported by the observation that animals inj. th flagellar antigen through the intestinal op respond to i.v. inj. in a characteristic condary-type manner. Early development of tibody-producing (plaque-forming) cells curred in the spleen of animals in which *S. senteriae* II antigen was inj. into the loop. though significant numbers of these cells also cumulated in the lymphoid tissue of the intes- nal loop, this did not occur until the splenic ll response and serum antibody titer declined. ese results provide little support for the pothesis that intestinal lymphoid tissue may ntribute significantly to the immunological sponse of animals to intestinal antigens.

224 SALMONELLOSIS COMPLICATING SCHISTOSOMIASIS IN EGYPT. A NEW CLINICAL APPRECIA- ON. (E.) Hathout, S. E. (Ein-Shams U., Cairo, ypt), Y. Abd El-Ghaffar and A. Y. Awny. *Amer. Trop. Med.* 16(4):462-472, 1967.

inical and laboratory studies of 61 patients th schistosomiasis and 21 patients without nistosomiasis, with infection with enteric ganisms, principally *Salmonella paratyphi* A, vealed that this infection complicated by nistosomiasis with hepatic fibrosis has a aracteristic picture, which is different from at of classic enteric infection in patients thout schistosomiasis. Of 61 with schistosomia- s, 10 (16%) had typhoid, 50 (82%) had paratyphoid and 1 (2%) had paratyphoid B. Most patients ve a history of sudden onset of illness; these so had fever of long duration, frequent chills d terminal hematuria. In most cases the liver s either decreased in size or, more commonly, derately enlarged. The spleen was enlarged d firm in all but 1 case. Abdominal examination d not reveal any significant tympanites or nderness, contrasting vividly with the abdomen cases of enteric infection in the absence of nistosomiasis. Treatment for enteric infection cluded 500 mg of chloramphenicol p.o., and for nistosomiasis, it was 12 i.m. inj. of a 6% soln. stibophen. Prolonged fever occurred in 35 of patients; after admin. of chloramphenicol the nperature returned to normal, but frequent apses occurred after 7-10 days of apyrexia ter cessation of the drug. Termination of fever ter therapy with chloramphenicol occurred rlier in patients with schistosomiasis than in se without it. In 35 with prolonged fever, od cultures were positive in 33: 2 with hoid and 31 with paratyphoid A. There was a lerate rise in the eosinophil count in patients h schistosomiasis and enteric infection. In cases, there were *Schistosoma hematobium* eggs the urine. In 16 of 17 cases of prolonged fever, enteric organisms were recovered from both blood and urine. Viable eggs of *Schistosoma mansoni* were found in the stools of 5 patients. Of 61 patients with schistosomiasis and enteric infection, 6 (10%) had the classic enteric fever, and 55 (90%) had a remittent type of fever. It was noteworthy that neither intestinal perforation nor bleeding was encountered in any of the 61 cases of schistosomiasis with enteric infection. The concept that enteric infection in patients with schistosomiasis is essentially a urinary-tract infection is strengthened by this study.

11225 ENHANCEMENT OF BACTERIAL INFECTION BY MECONIUM. (E.) Bryan, C. S. (Johns Hopkins U. Sch. Med., Baltimore, Md.). *Johns Hopkins Med. J.* 121(1):9-13, 1967.

When admin. to mice i.p. along with *Escherichia coli*, meconium consistently reduced the LD_{50} (organisms/mouse), compared to uncontaminated saline or amniotic fluid used for bacterial suspension. The factor by which the LD_{50} was reduced ranged from 7.5-6800 and, as with previously studied mucinous substances, it varied in direct proportion to the amount of meconium admin. When admin. intratracheally to rats along with *E. coli*, meconium reduced in each instance the number of bacteria required to cause death by bronchopneumonia. The magnitude of this effect paralleled that of the LD_{50} determinations in mice. Sterile meconium was never fatal in control experiments, although the statement that meconium has low-grade toxicity seemed substantiated from the external appearances of the animals. It is suggested that meconium reduces host resistance to bacterial infection in a manner similar to that of hog gastric mucin. Meconium may contribute to the course of infection in meconium peritonitis and meconium aspiration pneumonia.

11226 PATHOGENESIS OF *ESCHERICHIA COLI* ENTERITIS IN THE LIGATED RABBIT GUT. (E.) Drucker, M. M. (Shaare Zedeck Hosp., Jerusalem), R. Yeivin and T. G. Sacks. *Israel J. Med. Sci.* 3(3):445-452, 1967.

Six of 8 strains of *E. coli* which had been isolated from babies with infantile gastroenteritis produced accumulation of fluid within the intestinal lumen and inflammatory changes in the intestinal wall of ligated rabbit intestinal sections. These 10-cm alternate segments which had been inj. with an enteropathogenic strain of *E. coli* were sometimes dilated; the dilatation became visible when the index of fluid accumulation was greater than 3. The dilated segments contained opalescent gray or bloody fluid and occasionally gas. Further study with these strains plus some from healthy babies showed a correlation between fluid accumulation, inflammatory changes in the intestinal wall, adherence of bacteria to the surface epithelium and penetration of bacteria into the deeper tissues. Thus the index of fluid accumulation may serve as an objective measure of enteropathogenicity. Immunofluorescent staining of bacteria in intestinal sections demonstrated the extensive adherence of some strains of E. coli to intestinal epithelium and the penetration of bacteria through the epithelium into the intestinal wall. This was confirmed by culturing the same strains from mesenteric venous blood while cardiac blood remained sterile. It is possible that the ability of these strains of E. coli to adhere to the intestinal epithelium or to penetrate it (or both) may explain their enteropathogenicity.

11227 SALIVARY FLOW RATES AND IODIDE TRAPPING CAPACITY IN PATIENTS WITH SJÖGREN'S SYNDROME. (E.) Mason, D. K. (Western Infirm., Glasgow, Scotland), R. McG. Harden, J. A. Boyle, M. K. Jasani, J. Williamson and W. W. Buchanan. Ann. Rheum. Dis. 26(4):311-315, 1967.

In 14 patients with confirmed Sjögren's syndrome, sialographic results, salivary flow rates, and saliva plasma ^{132}I ratios are reported with the view of determining the iodide-trapping capacity in this condition. Sialography was normal in 5 patients and abnormal in the remaining 9 patients, with sialectasis being punctate in 1 patient, globular in 2 patients and cavitary in 3 patients. Seven of these 9 patients demonstrated atrophic changes. Salivary flow rates in 83 normal subjects as measured under conditions of rest, as well as under fruitgum and lemon juice stimulation were 0.059 ± 0.039, 0.36 ± 0.92, 1.70 ± 0.69 ml/min., resp. Under resting conditions in 8 patients with Sjögren's syndrome, there was no saliva measurable, 7 of these patients having abnormal sialograms. Under stimulation (both types) 8 patients, all of whom had abnormal sialograms, showed abnormally low salivary rates. In 3 of these latter patients, no salivation was observed after max. stimulation; two of these patients showed cavitary and 1 showed globular abnormalities, resp. All 5 patients with normal sialograms revealed normal flow rates, however. There was an indirect relationship between sialography and the saliva plasma ^{132}I ratio. Only 1 patient with an abnormal sialogram (severe cavitary changes) had an abnormal saliva plasma ^{132}I ratio. The remaining 5 patients with both Sjögren's syndrome and abnormal sialograms had ratios which were not significantly different from normal values. These findings indicate that there is no change in the salivary trapping capacity of iodide in Sjögren's syndrome, except in cases which present severe sialectasis.

11228 HEMORRHAGE AND NECROSIS OF THE STOMACH AND BOWEL DUE TO ATHEROEMBOLISM. A CORRELATIVE STUDY OF ATHEROMATOUS EMBOLI TO THE GASTROINTESTINAL TRACT IN HUMANS AND EXPERIMENTAL ANIMALS. (E.) Anderson, W. R. (Hennepin County Gen. Hosp., Minneapolis, Minn.), A. M. Richards and L. Weiss. Amer. J. Clin. Path. 48(1):30-38, 1967.

Widespread embolization of cholesterol is described in 3 patients (all male; 65-74 yr. old) in whom involvement of the gastrointestinal tract was shown by minute mucosal hemorrhages, necrosis and re-epithelialized ulcers. Two of the patient had progressive wt. loss and recurrent episodes of melena from an undetermined site; autopsy revealed widespread multiple-system atheromatous embolization, including extensive involvement of the stomach and the large and small intestines. Embolized submucosal arteries and arterioles were occasionally associated with minute re-epithelialized mucosal ulcerations, and rare gastric microinfarcts were found in 1 patient. In correlative experimental studies, gastrointestinal lesions were readily produced in rabbits (New Zealand strain) after inj. of atheromatous suspension (20-45 mg/ml) by retrograde aortic catheterizatic The kidneys and gastrointestinal tract were uniformly and most extensively involved and the severity and extent of the lesions paralleled th conc. of atheromatous suspension inj. Although these lesions were often severe and extensive, those of lesser degree which had been induced by the more dilute suspensions closely simulated those seen in the 3 patients described. These observations indicate that embolization of cholesterol to the gastrointestinal tract may be frequent and significant, but difficult or impossible to detect clinically and radiographical they may be overlooked easily at autopsy because of the minute size, transient nature and rapid re-epithelialization of the resultant lesions. Recurrent melena, which was a prominent feature in 1 patient, seemed to be accentuated by anticoagulant therapy; it is therefore suggested tha use of anticoagulants in patients manifesting multiple-system embolic phenomena, possibly resulting from cholesterol crystals, is contraindicated.

11279 PRESSURE CHARACTERISTICS OF REFLUX ESOPHAGITIS. (E.) Affolter, H. (U. Clin. Basel, Switzerland). Helv. Med. Acta 33(5): 395-402, 1967.

Esophageal pressure studies and esophagoscopy were performed on 48 patients (22 men, 26 women; 21-69 yr. old) with reflux esophagitis; there were 28 with mild esophagitis characterized by hyperemia, edema and friability of the esophageal mucosa and 20 with severe esophagitis, which, in addition, showed ulceration and/or bleeding. Findings of esophagoscopy were correlated with esophageal pressure studies. The degree of esophageal motor dysfunction paralleled to some degree the severity of the esophagitis. Patients with mild esophagitis showed, as a rule, normal motor activity or evidence of spastic motor incoordination of the esophagus and its lower sphincter after swallowing. In most patients with severe esophagitis, deglutition was followed by weak, often simultaneous, contractions of the distal esophagus and impaired relaxation and contraction of its lower sphincter. Complete motor failure of the esophagus was seen in a small number of patients with severe esophagitis. Manometric studies in reflux esophagitis are not primarily of diagnostic value, but they may be used as a guide to treatment.

11280 HIATAL HERNIA IN INFANTS. (E.) Lilly, J. R. (George Washington U., Washington, D. C.), J. LoPresti and J. G. Randolph. Southern Med. J. 60(5):545-548, 1967.

A series of 35 children less than 1 yr. old with esophageal hiatal hernia is described; diagnosis was by upper gastrointestinal X-ray series in each case; all were sliding hernias and all children were symptomatic from the hernia. The mean follow-up in this series was 13 mo. Major presenting symptoms included vomiting in 34 (97%), failure to thrive in 19 (54%), aspiration pneumonia in 11 (31%) and bleeding in 13 (37%). Esophagoscopy was performed on 15 (43%) of the patients. Initially all 35 patients were given a trial of conservative medical management; this included maintenance of continual upright position (angle of 60°) for at least 3 mo., and small, thickened and frequent feedings; 24 patients responded satisfactorily and were considered medical successes because of reversal of symptoms; there were 11 failures and 1 death. Ten of the 35 children required surgical correction of the hiatal hernia because of failure of medical management. In all cases an Allison method of repair (utilization of the phrenicoesophageal ligaments and posterior approximation of the crura) was used; the surgical approach was equally divided between the abdominal and thoracic routes. Pyloroplasty was done in 3 patients. Surgical treatment was successful in all cases. It is concluded that hiatal hernia of the esophageal hiatus is a surprisingly common gastrointestinal abnormality in children, and is commonly overlooked as a cause of certain gastric symptoms in early infancy.

11281 PECULIARITIES OF MOTOR FUNCTION OF THE SMALL INTESTINE IN PATIENTS WITH A ARTIFICIAL ESOPHAGUS CONSTRUCTED AFTER THE ROUX-HERZEN-JUDIN TECHNIC. (Rus.) Rusanov, A. A. (Leningrad Pediat. Med. Inst., USSR), N. A. Ivanova and B. T. Kats. Vestn. Khir. Grekov. 98(6):10-14, 1967.

The cancerous esophagus of 35 patients was remov (4 mo.-7 yr. previously) by the method of Roux, Herzen, and Judin and an artificial esophagus wa formed from jejunum. In 32 cases the esophagus was connected directly to the small intestine, excluding the stomach and duodenum. Difficulti in digestion or evacuation did not occur in 26 these persons; 8 had moderate difficulties afte eating; and 1 had steady hunger plus a markedly decreased level of serum albumin. X-ray examina tions revealed that the deglutition of all patients was normal. In those patients without digestive problems, $BaSO_4$ suspension passed easily through the natural portion, through the anastomosis, and the artificial part of the esophagus; it then penetrated into the jejunal loops. Intensive peristalsis of the artificial part of the esophagus was observed. Food mixed with $BaSO_4$ or plain $BaSO_4$ was not retained at the site of anastomosis. Backward penetration of the food through the duodenum into the stomach occurred very rarely. The passage of the food through the small intestine was slowed down by 2-16 hr. and the food was partially retained in reservoir-like enlargements formed in some of the jejunal loops; the food reflex of these patients was decreased or abolished. Apparently the delayed passage of food through the intestinal tract plays an important role in the restoration, after surgery, of the digestive function. In patients with moderate digestive difficulties, delayed passage of the food through the small intestine and the formation of reservoir-like enlargements in the intestinal tract were not observed; the food reflex of these patients was marked. In the patient, who suffered from serious digestive difficulties, an accelerated passage of the food through the intestinal tract occurred and the food reflex was extremely pronounced.

11282 ESOPHAGEAL DYSFUNCTION IN DIABETIC NEUROPATHY-GASTROENTEROPATHY. CLINICAL AND ROENTGENOLOGICAL MANIFESTATIONS. (E.) Mandelstam, P. (U. Kentucky Coll. Med., Lexington) and A. Lieber. J.A.M.A. 201(8):582-586 1967.

14 patients with diabetic neuropathy-gastro- teropathy, cineradiographic examination of the ophagus revealed clearcut signs of esophageal sfunction in 12 cases. In marked contrast to is high incidence of dysfunction, symptoms re- rable to the esophagus were present in only 3 tients: substernal burning upon ingestion, e sensation of slow passage of food through e suprasternal notch and dysphagia. The primary ristaltic wave was absent in 3 patients and re- ced in 9. Tertiary contractions were frequent 1 and occasional in 6. There was delayed ophageal emptying in the recumbent position in patients; in 2 of these, emptying was also de- yed when they were recumbent. Five patients ibited slight dilatation of the esophagus. No ient exhibited a breach in the cricopharyngeal incter or any cineradiographic evidence of dys- ction in the initiation of swallowing. The n age of the patients was 45 yr.; 6 were under e age of 35 yr. and only 5 were over 50. The n known duration of diabetes mellitus was 16 and the mean known age of onset of diabetes litus was 16 yr. and the mean known age of et of diabetes was 29 yr. Except for insulin, e patients were receiving no medications at the e of testing.

83 RELEVANCE OF DIAGNOSTIC PNEUMOMEDIASTINUM AS A METHOD FOR EXAMINATION OF ESOPHAGEAL EASES.

(Cz.) Holub, E. (Palacky U., Olomouc, choslovakia) and C. Šimeček. Cas. Lek. Cesk. (24):640-643, 1967.

parallel with X-ray examination and esophag- opy, diagnostic pneumomediastinum was used to study 56 patients with esophageal diseases with cancer of the esophagus and of the phagocardial sector, 17 cases with benign tumors the esophagus, and 5 cases with compression the esophagus by metastases of a bronchogenic cinoma). This method is designed mainly for examination of the outer esophageal wall. lowing bronchoscopy, the pertracheal insuf- tion into the mediastinum was carried out by . of 250 ml O_2 through a long needle intro- ed between the tracheal and the esophageal ls. After the insufflation the bronchoscope h the needle was removed and stratigraphic mination was performed. The negative contrast the insufflated O_2 made it possible to visualize outer wall of the esophagus, whereas the inner l was visualized by swallowed $BaSO_4$ suspension. gnostic pneumomediastinum permits assessment the size, and the shape of the esophageal or with a high degree of accuracy. It is also sible to determine by this method whether the or did or did not propagate into the adjacent ans; here a negative finding is much more re- ble. This method can be used also for follow- the effect of X-ray therapy on esophagus ors and is suitable to estimate the size of lymph nodes in the mediastinum and to dif- entiate increased nodes due to inflammation m those enlarged due to metastatic growth. method has only a limited value for diagnosis esophageal diseases other than cancer.

11284 STUDIES ON THE LETHAL COMPLICATIONS OF HIATUS HERNIA.

(Ger.) Kieser, C. (U. Zurich). Gastroenterologia (Basel) 107(5): 328-336, 1967.

The incidence and mortality of hiatus hernia in Switzerland is surveyed. Annual mortality is 8.1/million residents, about 6.7% that of gastric and duodenal ulcers or 7.7 of that from cholelithiasis; 4.6 deaths/million/yr. occur in relation to surgery for hiatus hernia; the remainder, 3.7 deaths/million/yr., occur mainly among children dying from persistent vomiting, aspiration pneumonia or esophageal stricture in adults, not operated upon, the hernia is not more than a contributory cause of death. Lethal complications of hiatus hernia observed in 22,003 autopsies performed during a 10-yr. span included 14 deaths resulting from hernia surgery, 5 from esophagitis, 1 from aspiration pneumonia, 1 from cardia carcinoma, 3 from esophageal ulcers, and 2 from gastric ulcer; a total of 26. The mortality in the author's practice during operation on 344 patients was 2.7%; postoperative deaths were 14 and included 4 from perforations in the field of operation, 4 from lung emboli, 2 from anesthetic accident (postoperative apnea) and 1 each from bronchopneumonia, hemorrhage due to increased clotting time, staphylococcus-infection enteritis, and collapse of unknown origin.

11285 EXPERIMENTAL CONTRIBUTION TO THE RECONSTRUCTION OF THE CLOSING MECHANISM AFTER MYOTOMY OF ESOPHAGOGASTRIC JUNCTION.

(Cz.) Kralik, J. (Palacky University, School of Med., Olomouc) and T. Kofanova. Cas. Lek. Cesk. 106(24):644-647, 1967.

Radical myotomy by Heller's method should be performed in operations of esophageal achalasia. Since, radical myotomy eliminates the dysfunctional sphincter of the esophagogastric junction, the reconstruction of the closing mechanism of this junction was investigated. Eight dogs were operated upon using left-side thoracotomy; the esophagogastric junction was released and on its left, anterior part, extra mucosally, a longitudinal myotomy was performed. The myotomy covered the entire region of the closing mechanism and reached to the stomach; the Helvetius muscle of 4 of the 8 dogs was also cut. The Dor-Thal and the Jezior methods were used for the reconstruction of the closing mechanism in each of 4 animals. The dogs were observed for up to 27 wk. after the operation; they did not show any symptoms of dysphagia and X-ray examination of the stomach and esophagus was performed at various intervals (9-37 days) after surgery. The $BaSO_4$ suspension passed easily through the esophagus and the esophagogastric junction; reflux from the stomach into the esophagus did not occur. Seven dogs were sacrificed 1-26 wk. after surgery where the esophagogastric junction and the gastric fundus were seen to be firmly fixed below the diaphragm and the formation of abdominal esophagus was clearly discernible. Esophagitis was not detected. The results of the present study may be of clinical importance since the conditions for the reconstruction of the closing mechanism are more favorable in man than they are in the dog.

11312 A CHROMATOGRAPHIC MODIFICATION OF THE TETRACYCLINE FLUORESCENCE TEST FOR GASTRIC CANCER. (E.) Ibsen, K. H. (U. California, Los Angeles), J. E. Berk and A. M. Morimoto. Cancer Res. 27(7):1296-1300, 1967.

Separation of demethylchlortetracycline from fluorophores native to many samples of human gastric sediment was achieved by cellulose column and paper chromatographic technics; these technics were devised to enhance the crude tetracycline test for gastric cancer by making it quantitative and objective. Gastric sediments obtained from 29 subjects without gastric cancer and 9 patients with proved gastric cancer, after the prior admin. of demethylchlortetracycline (150 mg, 4 times/day for 5 consecutive days p.o.), were examined by means of these chromatographic methods. Paper chromatography demonstrated demethylchlortetracycline fluorescence only in the samples obtained from patients with gastric cancer. Quantitative estimation of demethylchlortetracycline also showed that the amount recovered from the sediments of the cancer patients was in each case significantly greater than in the noncancer subjects (2.2-20 µg/ml in cancer against 0-0.9 µg/ml in noncancer patients). These preliminary observations suggest that the chromatographic methods described may provide a basis for performing the tetracycline fluorescence test for gastric cancer with greater specificity and reliability.

11313 5-FLUOROURACIL THERAPY FOR CANCER OF THE STOMACH. (E.) Blokhina, N. G. (Inst. Exp. Clin. Oncol., Moscow) and N. N. Blokhin. Cancer 20(5):668-672, 1967.

Over a 3-yr. period, 250 patients were treated with 5-fluorouracil for advanced gastric carcinoma; good results (tumor regression and improved general status) were obtained in 50% of the cases. In some cases, roentgenologic studies showed complete disappearance of the tumor. These results differ from published reports of chemotherapy of gastric neoplasms, which generally report low sensitivity of gastric carcinoma to 5-fluorouracil. Since the drug is markedly toxic, its use is limited, but methods developed at the Institute for Experimental Clinical Oncology made it possible to decrease the toxic effects. The basic regimen of treatment consisted of daily i.v. inj. of the drug on consecutive days (15 mg/kg; no single dose exceeding 1 g), and then half of the dose was admin. every other day for a total of 2-3 admin., until the first symptoms of toxicity appeared; each patient received a total dose of 5-7 g of 5-fluorouracil. The admin. of the drug every other day lessens its cumulative effect, which in turn allows increasing single doses without a consequent rise in toxicity. The action of 5-fluorouracil was greater in treating primary tumors and relapses, and was less pronounced in its effect in the treatment of metastases. It is suggested that combined chemotherapy (use of 5-fluorouracil and agents with other mechanisms of action) will give better results.

11314 GASTRIC CANCER AND DIET. A PILOT STUDY ON DIETARY HABITS IN TWO DISTRICTS DIFFERING MARKEDLY IN RESPECT OF MORTALITY FROM GASTRIC CANCER. (E.) Dungal, N. (U. Iceland, Reykjavik) and J. Sigurjonsson. Brit. J. Cancer 21(2):270-276, 1967.

In questionnaires covering approx. a 10 yr. period given to the closest possible relatives of people dying from gastric cancer in 2 districts of Iceland, emphasis was placed on the total consumption of smoked and singed foodstuffs along with the frequency of preparation of all common foods during the summer and winter seasons, the number of animals killed for home use and the number of carcasses smoked. The smoked food consumption in the 2 districts did not differ significantly, with the mean frequency of total consumption being the same. Singed food consumption was higher in the area which evidenced the higher standardized mortality rate for gastric cancer (Northern district with a rate of 143.7 and southern district with a rate of 75.5). A variation pattern in the various types of foods (smoked and salted foods, singed sheep heads, potatoes) prepared and served was observed between the 2 districts. The 3,4-benzopyrene levels of smoked and singed foods was higher also in the northern district than in the southern. In addition, vitamin C intake was lower in the northern district. No clear evidence of a difference in milk consumption was noted. The decline in the incidence of gastric cancer observed during recent decades may be related to a reduced exposure on an increased part of the population to 3,4-benzypyrene such as is found in smoked and singed foods. A further study is required to ascertain whether the positive association revealed in this study between the incidence of gastric cancer and the levels of 3,4-benzopyrene found in common foodstuffs can be observed in other parts of Iceland.

11315 GASTROSCOPIC MANIFESTATIONS OF PANCREATIC TUMORS. (Pol.) Foremny, Z. (1st Intern. Dis. Clin., Katowice, Poland) and M. Machalski. Pol. Tyg. Lek. 22(34):1290-1292, 1967.

Among 1500 gastroscopies 45 abnormal findings were caused by pancreatic tumors (19 malignant, 25 inflammatory, 1 cyst). Signs of pressure and impressions in the stomach wall caused by pancreatic tumors can easily be recognized by means of gastroscopy. It allows exact evaluation of the condition of the gastric mucosa and facilita diagnostic exclusion of primary gastric neoplasm In 14 cases of inflammatory tumors and 4 cases arcinoma changes of the mucosa were discovered astroscopic examination which were not aled by radiology; in a few cases it showed sure and bulging of the stomach wall which not visible during radiological examinations. gnant tumors were frequently well-defined bulged into the gastric lumen as oval, well-neated structures while inflammatory tumors ed more extensive but less well-defined ing of the posterior wall of the stomach, r part of the fundus and the prepyloric seg-. The mucous membrane in cases of inflammatory rs is swollen and hyperemic with no erosions se usually result from neoplasms). It is luded that in all cases of suspected pan-tic carcinomas, cysts, or inflammatory tumors, roscopic examination should be performed.

6 EPIDEMIOLOGICAL ASPECTS OF CANCER OF THE STOMACH IN ISRAEL. (E.) Tulchinsky, Tel Hashomer Govt. Hosp., Israel) and B. n. Cancer 20(8):1311-1317, 1967.

are presented on the distribution of cancer he stomach in Israel for 1961-1963. The gnancies of 1172 Jewish and 33 Arabic patients diagnosed, yielding an incidence rate of /100,000 for males and 15.0 for females. youngest patient in the total group was 22 at diagnosis, and the oldest was 105 yr.; of patients, 1.2% were younger than 35 yr. and were 85 and older. Until age 35 there was eponderance of females with a male:female ratio of 0.4:1, in contrast to the overall o of 1.6:1. The incidence was significantly er in residents of European extraction with a pe:Africa age-adjusted ratio of 1.3:1 and a pe:Asia ratio of 1.8:1. In all population ps the incidence of the disease was signifi-ly higher in new immigrants compared to ran immigrants. A higher proportion of nite cases, diagnosed on a histopathologic s, relative to probable cases, diagnosed ically, was noted in males than in females; ological confirmation of cancer of the stomach significantly more prevalent among males 7%) than among females (54.5%). A higher ortion of definite cases relative to probable s was also observed in younger than in older groups and in immigrants coming from Europe in those coming from Asia and Africa.

7 SIALIC ACID IN THE GASTRIC JUICE OF THE PATIENTS WITH GASTRIC CANCER. (E.) , T., T. Nishida, H. Tamura, H. Inui and N. a. Ann. Rep. Ctr. Adult. Dis. (Osaka) 03-108, 1965.

g a combination of ion exchange resin matography and a very sensitive thiobarbituric assay, sialic acid was estimated in the ric juice from normal subjects and from ents with a variety of gastric lesions. The . of sialic acid (mg/100 ml) in 82 normal rols was 4.5 ± 0.26, while in 46 cases of gastritis it was 5.0 ± 0.28, 23 cases of atrophic gastritis, 5.9 ± 0.33, 98 cases of gastric ulcer, 4.6 ± 0.38, gastric polyp (5 cases), 4.3 ± 0.27, 52 cases of gastric cancer, 5.4 ± 0.86 and 14 cases of duodenal ulcer, 4.3 ± 0.24. In gastric cancer specimens, as well as in those with atrophic gastritis and histamine-fast achylia, there were increased levels of sialic acid, while in gastric ulcer and gastric polyp the levels were within the normal range. Of the various types of gastric cancer, Borrmann type III demonstrated an increased amount of sialic acid in the gastric juice; sialic acid values were within normal range in other types of gastric cancer. The adenomatous muconodular type of Borrmann type III contained a much greater amount of sialic acid than normal gastric mucosa; however, in the scirrhous type, sialic acid content was less than in normal gastric mucosa of resected stomachs.

11318 THE THICKNESS OF THE GASTRIC MUCOSA IN BIOPSY MATERIAL. (Ger.) Wolff, G. (Robert Rossle Clin., Berlin). Gastroenterologia (Basel) 107(4):235-241, 1967.

One stomach biopsy specimen was measured in 294 cases and 2 or more measured in 119 cases; the tissues were fixed, embedded under uniform conditions and measurements were made from the surface of the mucosa to the base of the gastric glands. Accuracy of measurements was tested by comparing values obtained from 1 histologic section with those from another section of the same person in 10 cases. The av. height of the mucosa proper (not including the muscularis mucosae) was 0.67 mm in 110 normal persons and 26 near normal (slight indication of infiltration). Those with any degree of gastritis (about 175 patients) had mucosae significantly thicker than normal (0.71-0.72 mm) whereas the approx. 102 with chronic gastritis including cases with partial and complete atrophy had an av. of 0.55 mm. The confusion in patient numbers arises from the omission of data on the numbers of patients with exact numbers of multiple biopsies.

11319 IN VITRO STUDIES ON ANTIBODIES TO INTRINSIC FACTOR. (E.) Schade, S. G. (U. Wisconsin Med. Sch., Madison), P. L. Feick, M. H. Imrie and R. F. Schilling. Clin. Exp. Immun. 2(4):399-413, 1967.

In vitro experiments on anti-intrinsic factor antibodies in the sera from patients with pernicious anemia were studied. Antibody I was found to be on a different molecule from antibody II, the latter uniting with either intrinsic factor or with intrinsic factor-B_{12}. Antibody I exchanges readily with the B_{12} of intrinsic factor-B_{12}. The complex intrinsic factor and antibody I will absorb Antibody II. These data support the conclusion that the intrinsic factor has at least 2 antigenic regions. An unusual type of antibody activity is also reported, one which seems to stabilize B_{12} on intrinsic factor so that exchange of $B_{12}{}^{59}Co$ or Antibody I with the $B_{12}{}^{57}Co$ of intrinsic factor-$B_{12}{}^{57}Co$ is inhibited. This antibody forms a complex with intrinsic factor-B_{12} as well, the latter being of a different size from other Antibody II-intrinsic factor-B_{12} complexes.

11320 MORPHOLOGY OF THE GASTRIC MUCOSA OF THE DOG AFTER IMMUNIZATION WITH AUTOLOGOUS GASTRIC JUICE. I. HISTOLOGICAL STUDY. (E.) Langr, F. (Charles U., Hradec Kralove, Czechoslovakia), B. Fixa, O. Komárková, J. Pařízek, O. Vejbora and I. Hradil. Path. Microbiol. (Basel) 30(4):419-424, 1967.

The immune mechanism of the delayed sensitivity kind is involved in the development of gastric atrophic changes. Four mongrel dogs of both sexes and of various ages were immunized with autologous lyophilized gastric juice with complete Freund's adjuvant. Histological inspection of the gastric mucosa showed marked edema of the interstitium, degenerative changes of parietal cells and infiltration of the interstitium by small cells. Specifically, changes in the parietal cells included anisochromy and a lowered staining of the plasma, vacuolization, karyorrhexis and pyknosis. It is remarkable that, in the period of max. atrophic changes, only a slight inflammatory reaction was found. Parietal and chief cells decreased in number.

11321 MORPHOLOGY OF THE GASTRIC MUCOSA OF THE DOG AFTER IMMUNIZATION WITH AUTOLOGOUS GASTRIC JUICE. II. HISTOCHEMICAL STUDY. (E.) Pařízek, J. (Charles U., Hradec Kralove, Czechoslovakia), B. Fixa, O. Komárková, F. Langr, I. Hradil and O. Vejbora. Path. Microbiol. (Basel) 30(4):425-432, 1967.

The distribution and activity of the enzymes in the normal gastric mucosa of 4 dogs after immunization with autologous lyophilized gastric juice was evaluated. During immunization significant changes in distribution and activity of certain hydrolytic enzymes occurred; marked changes were seen in the activity of acid phosphatase and nonspecific esterase. A mo. after antigen admin. the activity of acid phosphatase was high at the surface epithelium and in the glands, particularly in the parietal cells. Nonspecific esterase activity was depressed in surface epithelium. After several mo., atrophic changes developed and the activity of acid phosphatase increased to a marked degree in the neck cells. Activity of the dehydrogenases decreased in some parietal cells when atrophy occurred.

11322 AN IMPROVED G. I. CORD FOR THE DETECTION OF UPPER GASTROINTESTINAL BLEEDING. (E.) Bray, R. S. (Rhode Island Hosp., Providence). Amer. J. Proctol. 18(4):277-287, 1967.

To obviate those difficulties experienced in swallowing the original gastrointestinal cord ar to prevent discomfort caused by the excessively dry mouthpiece, modifications were studied. The new mouthpiece consists of a 2-ft. length of extruded rubber core without any metallic markers or outer cotton sheath. The distal rubber core is 2 ft. in length and is calibrate with metallic markers at 2-inch intervals and covered with an outer cotton sheath. The new-w apparatus is composed of bronze and is nickle-plated. It is drilled with 2 borings, 1 to permit passage of the cord itself and the other which fits tightly around the knotted tape at the end of the cord. Use of i.v. admin. of fluorescein dye is generally confined to those cases showing hematemesis, melena or deep positive-stained stools. The cord is extremely useful in the detection of these lesions of the upper gastrointestinal tract which manifest variable hemorrhage. Seventy ambulatory patients with sliding hiatal hernia (23), gastritis (5), peptic ulcer (35), prolapse of the antral folds (2), duodenal-jejunal diverticula (2) and esophageal varix (1) were evaluated wit the use of the new gastrointestinal cord. In slow bleeders, the blood stain appeared to be clotted and was of deeper color and greater intensity than that obtained from patients with more profuse hemorrhaging, thus a reduced test time was observed.

11323 GASTRIC ARTERIO-VENOUS SHUNTS. AN INVESTIGATION USING A DYE DILUTION TECHNIQUE. (E.) Bell, P. R. F. (Western Infir Glasgow, Scotland). Scand. J. Gastroent. 2(1): 59-67, 1967.

The function of gastric submucosal arteriovenou shunts was studied in 26 mongrel dogs by the inj. of a bolus of dye into the arterial side of the gastric circulation and its subsequent collection from the veins, so that a dilution curve was obtained of its passage across the gastric vascular bed; 0.6 mg indocyanine green in 0.5 ml distilled water at 37°C was inj. rapidly into the celiac axis after momentary occlusion of the vessel. Evidence of shunt activity was taken as a rapid transit time or double peak curves. The results suggest that under basal conditions evidence of functional arteriovenous shunts occurred in some animals; basal curves showed double peaks in only 2 dogs since basal curves of various types were obtain the effect of intermittent occlusion of the celiac axis, if any, was minimal. Histamine acid phosphate (infused at 1 µg/kg/min. or admin. s.c. at 1.0 mg) appeared to close shunts if they were open and divert blood through othe slower channels. Epinephrine (infused at 1 µg/kg/min., or admin. by repeated i.v. inj. of 0.25 ml of 1:10,000 soln.), vagal stimulatio vagotomy and hepatic anoxia (obtained by occlusion of the hepatic artery for periods of 5-10 min.) did not appear to have any effect on shunt activity. No evidence was found to suppo the view that shunts respond in a uniform manne to control mucosal blood flow.

24 RELATIONSHIP BETWEEN LESION PRODUCTION,
ABSORPTION, AND DISTRIBUTION OF C-
ELED ACETYLSALICYLIC ACID. (E.) Morris, E.
rdue U., Lafayette, Ind.), A. A. Noujalm,
S. Miya and J. E. Christian. J. Pharm. Sci.
7):896-899, 1967.

-Carboxyl-labeled acetylsalicylic acid was
pended in 5% polyvinylpyrrolidone and admin.
. to 24 male Holtzman rats in doses of 10-600
kg; control animals received similar doses of
yvinylpyrrolidone alone. The conc. of
tylsalicylic acid in the rumen and corpus
tions of the stomach and in other tissues was
ermined for various time intervals after admin.,
ng liquid scintillation counting and auto-
iography; the localization of the drug was
died in both the mucosal and muscularis sur-
es of the stomach. Acetylsalicylic acid in
es of from 50-600 mg/kg produced gastric
ions in the corpus portion of the rat stomach.
tylsalicylic acid was absorbed through the
osa of the corpus portion at a rapid rate,
n max. conc. being reached within 5 min. after
g admin. The conc. of the drug in the mucosa
the rumen portion remained relatively constant
r a 3-hr. period after admin., while the conc.
the corpus was initially high with a steady
rease beginning 5 min. after p.o. admin.;
drug conc. decreased in the corpus portion
a level comparable to that found in most
er tissues after approx. 1 hr., while in the
en it remained at a significantly higher
el. These findings tend to refute the hypoth-
s of focal necrosis, at least as the sole
hanism of gastric erosion. These findings
d to support the concepts of Davenport as to
importance of tissue permeability and ion
x across the mucosa in the production of
illary wall damage eventually resulting in
od loss and erosion of the mucosa.

5 A JEJUNAL POUCH AS SUBSTITUTE STOMACH
AFTER TOTAL GASTRECTOMY. AN EXPERI-
TAL STUDY IN RATS. (E.) Helsingen, N., Jr.
ate Hosp., Oslo) and K. Nygaard. Scand. J.
troent. 2(1):18-22, 1967.

ng adult male rats were subjected to 3 opera-
e procedures: 1) total gastrectomy, with a
x-en-Y reconstruction; 2) total gastrectomy,
x-en-Y reconstruction, with an additional
unal pouch; and 3) pylorectomy, with Roux-en-Y
onstruction. Unoperated rats served as con-
s. These groups of animals were compared
n regard to postoperative intake of food,
y wt., hemoglobin conc. and length of survival.
ood-sized jejunal pouch was present in all
nals at autopsy. After total gastrectomy,
re was no significant difference between the
toperative course in rats with and without a
unal pouch. However, rats with the fore-
mach intact showed a significantly greater
ake of food and body wt., and survived longer
n totally gastrectomized rats; therefore,
s "ideal food pouch" seemed to demonstrate
the importance of a food reservoir in the rat. The normal controls survived longer than any of the other groups, probably demonstrating the importance of the secretory function of the stomach.

11326 EXPERIENCE ON GASTRECTOMY WITH ANTEROCOLONIC GASTRO-ENTEROANASTOMOSIS WITHOUT ENTERO-ENTEROANASTOMOSIS. (Rus.) Frumgarts, A. N. (Cent. Inst. Postgrad. Med., Moscow). Vestn. Khir. Grekov 98(6):23-27, 1967.

During 1956-1965 gastrectomy (Billroth II) with the anterocolonic gastroentero-anastomosis but without entero-enteroanastomosis was performed on 255 patients; 203 of them had ulcer diseases of the duodenum or of the stomach, 47 stomach cancer, and 5 gastric polyposis. Up to the end of 1962 anastomosis was applied on 10-12 cm-long ansa (144 operations), later on 25-30 cm-long ansa. In the case of ulcer disease an av. of 66% of the stomach was removed whereas with cancer almost the whole stomach was removed. After surgery 2 patients died (bleeding into the abdominal cavity; peritonitis). Dysfunction of the anastomosis (regurgitation, retching), lasting up to 3 days, occured in 21 patients; these could be removed by gastric lavage. Prolonged (4-10 days) regurgitations, occurring in 4 patients, could be eliminated by the same treatment. Two patients had adhesive obstruction which had to be removed by surgery. All patients with evacuation difficulties were cured. Further complications occurring and being treated after surgery were: bleeding into the gastrointestinal tract (8 patients), pneumonia (1), abscess of the abdominal cavity (2), suppuration of the wound (1), and thrombophlebitis of the lower extremity (1). Complications involving the cardiovascular system were not observed, although 93 patients were more than 40 yr. old. Complications involving the liver or the pancreas were absent. Blood and gastric juice analyses, X-ray examination of the gastrointestinal tract, and other tests were observed in 166 patients for 1-10 yr. Dumping syndromes of various intensity occurred in 30 patients and disappeared in 27 of them after appropriate diet. In 7 patients gastritis was detected, 2 had colitis, and 7 hepatitis or hepatocholecystitis. Recurrence of ulcer disease were not observed. Former activities could be resumed in 92% of all patients.

11327 pH AND CONCENTRATION OF PANCREATIC ENZYMES IN ASPIRATES FROM THE HUMAN DUODENUM DURING DIGESTION OF A STANDARD MEAL. IN PATIENTS WITH DUODENAL ULCER AND IN PATIENTS SUBJECTED TO DIFFERENT GASTRIC RESECTIONS. (E.) Worning, H. (Blegdam Hosp., Aalborg, Denmark), S. Müllertz, E. H. Thaysen and H. O. Bang. Scand. J. Gastroent. 2(1):23-38, 1967.

After ingestion of a standard meal, the intestinal contents were collected from each of 166 patients during 4 subsequent periods of 20 min. each; the vol., pH and the conc. of α-amylase, trypsin, chymotrypsin and lipase in the collections were determined. The 166 patients included 39 with duodenal ulcer, 113 with partial gastrectomy, which included 20 with a Billroth I gastrectomy and 93 with a Billroth II gastrectomy, 5 with a gastroenterostomy and 9 with total gastrectomy. The pH was not below normal in patients with duodenal ulcer. The results indicate an admixture of salivary to pancreatic amylase in the intestine of patients with gastrojejunostomy, particularly by concomitant hypoacidity. In all groups of patients, secretions of trypsin, chymotrypsin were closely related. In patients with partial or total gastrectomy, the secretion of lipase was more markedly reduced than the secretion of other enzymes. The mean conc. of lipase in the efferent loop in Billroth II patients was closely related to the absorption of fat. Depending upon the enzyme concerned, 10-20% of the patients with duodenal ulcer, and 21-50% of the patients subjected to Billroth II gastrectomy, had abnormally low conc. of enzymes in all collections. In these groups of patients, the mean conc. of the 4 enzymes was significantly reduced in all collections. In patients exposed to Billroth I gastrectomy, gastroenterostomy, or total gastrectomy, mean mean conc. of the enzymes were below normal levels in the first collection only.

11328 ALCOHOLISM OF SUBJECTS WITH GASTRIC RESECTION.

(Hun.) Péntek, L. (Regional Hospital, Eger, Hungary) and Z. Gáldi. Orv. Hetil. 108(11):503-504, 1967.

Before gastrectomy for previous ulcerous disease, only 13 of the 294 patients studied consumed alcohol regularly. After surgery the number of regular consumers (mainly of wine) increased to 132. The proportion of patients who reported digestive difficulties after resection was the same for the alcohol consumers and nonconsumers (9.1 and 9.0%). A marked relationship was found between the acidity of the gastric juice of the patients before the gastrectomy and the incidence of alcoholism after surgery. Among persons with hyperacidity, normal acidity, and hypoacidity, 54.7, 27.3, and 6.1%, resp., became regular alcohol consumers. A parallel investigation showed that 32 of 701 chronic alcoholics had undergone gastrectomy. It is emphasized that consumption of wine or other alcoholic beverages by persons after gastrectomy is not recommended.

11329 VAGOTOMY OF THE STOMACH. A TOPOGRAPHIC-ANATOMIC PROBLEM.

(Ger.) Kothe, W. (Ernst Moritz Arndt U., Greifswald, Germany) and A. Dorn. Zbl. Chir. 92(28):2163-2167, 1967.

Vagal innervation of the stomach was traced in 20 male cadavers (3-82 yr. old). A vagal plexus, was found about the thoracic esophagus and was supplied by both left and right vagi with massive mixing of the left and right fibers. On the lower thoracic esophagus just above the hiatus, the fibers of the plexus formed a trunk or a number of nerve trunks on the left anterior wall of the esophagus; from these arose 2 main nerves, 1 a right vagus and the other an anterior vagus (in 17 of 30 cases there was only 1 anterior trunk, in 11 2 nerve tracts were noted and in the remaining 2, 3 or 4 branches were present). The branching of the single anterior vagus trunk began somewhat above the cardia with 1 or more branches turning toward the left to the anterior wall of the fundus. The trunk itself turned toward the liver to which a number of fine branches passed. From the convexity of the trunk a number of branches passed alone the anterior edge of the lesser curvature to disappea in the anterior wall of the stomach. The terminal branching could be followed as far as the incisura. In 5 of 17 cases with a single anterior trunk a direct connection with the celiac ganglion could be demonstrated and in 9 of the 17 cases a connection with the lower stomach branches of the right vagus could be shown. When there were multiple nerves, the 1 to the right or those on the right sent long nerves to the liver and along the lesser curvature; in some cases nerves from the right branches entered the celiac ganglion and the lower branches of the right vagus trunk proper. When the multiple anterior nerves anastomosed with each other (7 of 13 cases) the gastric regions and the liver were supplied by nerves from the anastomosis. Branches radiating toward the left entered the fundus, turning caudad as far as the anterior wall of the stomach. In 15 cases the anterior trunk or trunks had connections with the celiac plexus and in 15 other cases with the right vagus trunk; 7 showed connections with both the ganglion and the right vagus trunk. The right vagus trunk was more regular than the anterior one. Below the hiatus a number of branches supplied the posterio wall of the cardia and the fundus. The right trunk was completely separated from the esophagus sending a thick nerve to the celiac ganglion; usually a smaller branch passed to the left becoming associated with the left gastric artery. A branch of this upon leaving the artery, entered the lesser curvature of the stomach and passed to the posterior region of the stomach. The branching nerves often form anastomoses.

11330 GASTRIC SURGERY IN ALBINO RATS. RESEARCH ON METHODS.

(Ger.) Maurer, W. (U. Polyclin. Erlangen, Germany). Z. Gastroen 5(3):183-188, 1967.

Technics in stomach operations were studied in 125 rats (180-250 g) fasted for 12 hr. prior to surgery and maintained in cages with screen flooring to prevent coprophagy. Animals with empty stomachs at the time of operation showed significantly fewer postoperative complications. Beginning on the day after operation each animal received 1.5 ml 3 times/day of a cocktail with the composition: 250 ml 5% glucose soln., 10 mg SP 366 (a spasmolytic), and 250 mg of oxytetracycline (Terramycin). SP 366 reduced pancreatic etion. The cocktails were continued for 7 ; water and food were available to the animals nning on the second day after surgery. Loss lood during surgery was prevented as the loss .5 ml represented 5% of the total blood vol.; gastrointestinal tract of the rat is cially subject to trauma. Ligature thread silk no. 4-0 and 5-0 used with a traumatic eal needles with the lightest needle holders the weakest pincers. All tissue layers were erly sutured for continuity. Operations in ral involved end-to-end anastomoses of the ach, duodenum and jejunum, and side-to-side tomoses. The vascularization of the stomach proximal small intestine is described and strated with special reference to the arteries. ial operative methods which are described in il include gastric resection according to roth I, according to Billroth II, and gas- resection with atypical anastomoses of the intestine; these were chiefly of the anti- staltic type (34 cases). The overall death in these surgical studies was 25%.

1 A COMPARATIVE ASSESSMENT OF OPTICAL AND FIBRE GASTROSCOPES. (E.) Kont, L. A. elbourne, Australia) and G. Berci. Med. Illus. 17(3):181-190, 1967.

rison by several photographic tests of 3 of gastroscopes, Schindler gastroscope flexible with a lens system), Hirschowitz gastroscope and the Eder fiber gastroscope, ated that the flexible fiber endoscope has in definite advantages but that further vements will be necessary before it can be dently recommended as being superior in all cts to standard instruments based on lens ms. With the Schindler, definition (image ness) was excellent; geometrical and optical duction good, and light transmission, fair; the Hirschowitz instrument, light trans- on, geometrical and optical reproduction excellent, resolution were good and ition was fair. With the Eder instrument, ution and geometrical reproduction was lent and optical reproduction, definition ight transmission were good. The total ter of the actual image seen through the r was 46 for the Schindler, 45 for the Eder 6 for the Hirschowitz and the magnification :1.5, 2:1 and 1:1.1, resp. The viewing (object distance 40 mm, lateral view) was 31° and 44°, resp.

CHANGES OF CATECHOLAMINE LEVEL IN GASTRIC WALL TISSUE IN REFLEX DIGESTIVE RBANCES. (E.) Zavodskaia, I. S. (Inst. Med., Leningrad, USSR) and E. V. Moreva. Pharmacol. Exp. (Basel) 16(5):399-402,

phic injuries were induced in male albino ed rats by combined immobilization and . of electrical current (rectangular impulses of alternating current, 6-7 volts) for 3 hr.; starved intact rats served as controls. After treatment, gastric wall tissue was removed and examined for catecholamine content. After admin. of electrical current to immobilized rats for 3 hr. there was a quantitative decrease of catecholamines in the gastric wall; this was particularly noted for norepinephrine. The level of norepinephrine in intact animals was 0.64/0.24 µg/g of wt. of damp tissue, while after strenuous irritation it diminished to 0.21/0.16 µg/g in 6 experiments and disappeared completely in 5 cases. Changes in epinephrine content in the gastric tissue were not as marked. It is concluded that excessive irritation, provoking development of destructive reflex impairment in the gastric wall, is accompanied by a decrease of the catecholamine level. Alterations in the balance of catecholamines may be regarded as 1 of the possible causes which elicit dystrophic processes in the gastric wall. These results are indicative of the important role played by the sympathetic nervous system in the development of neurogenous gastric wall dystrophies.

11333 FUNDIC RESECTION IN RATS AND ITS LONG TERM EFFECT ON DEVELOPMENT OF GASTRIC CANCER. (E.) Ackerman, N. B. (U. Hosp., Boston, Mass.). Gastroenterology 53(2):280-287, 1967.

Sprague-Dawley rats which were made hydrochloric acid-deficient by resection of the fundus of the stomach and anastomosis of the antrum to the rumen appeared to be more susceptible to the effects of the carcinogen methylcholanthrene or a chronic irritant HCl than were animals with intact stomachs, although they did not develop gastric malignancies after resection alone. In a group of 19 rats with fundic resection and which received 0.02 N HCl as the source of drinking water, 2 gastric cancers were identified; one was a squamous cell carcinoma and the other an adenocarcinoma of the stomach which penetrated to the serosa. In this group 6 had ulcerations. In a group of 23 animals which had fundic resections plus methylcholanthrene pellets (av., 7.0 mg) implanted in the antrum, gastric cancers also developed in 2 rats. Both tumors originated in the antrum; one was a fibrosarcoma involving all layers of the stomach and the other an adenocarcinoma that penetrated through to the serosal surface. Gastric ulceration was present in 4 of this group. Rats which received only pellet implants did not develop tumors although some superficial gastric ulceration was present in 7. Bone formation in the mucosa occurred in 17 rats from 3 groups (fundic resection, fundic resection plus acid, resection plus pellets).

11334 THE NORMAL GASTRIC AND DUODENAL RUGAE. RADIOGRAPHIC FINDINGS IN NON-DYSPEPTIC YOUNG PERSONS. (E.) Krag, E. (Aarhus Hosp., Denmark). Acta Med. Scand. 182(1):1-4, 1967.

The morphology of the gastric mucosa was studied radiographically in 94 (79 males, 15 females) healthy, nondyspeptic medical students who were 20-30 yr. old; the morphology of the duodenal mucosa was also studied in 59 of these subjects. In all subjects the fundus revealed slightly irregular mucosal folds; in the body and prepyloric region the course of the folds was largely regular and parallel to the curvatures. The width of the folds was less than 5 mm in all subjects but 1, in whom films taken in the dorsal position showed folds of a width of up to 7 mm, but the pattern was also regular. All of the subjects studied showed a normal duodenal bulb without signs of deformity or irritability; the folds of the bulb were regular and the remaining portion of the duodenum revealed the characteristic feather-boa pattern, except in 2 cases in which the duodenum was rather hypotonic, but with a regular mucosal pattern; all folds observed were less than 5 mm in width. It is concluded that in nondyspeptic subjects in the 20-30 yr. old age group, the gastric and duodenal mucosae show a regular mucosal pattern with nonrigid folds which are less than 5 mm in width.

11397 A TECHNIQUE FOR CONTROLLED SAMPLING OF SMALL INTESTINAL CONTENTS. (E.)

Wiggins, H. S. (Cent. Middlesex Hosp., London), H. Bramwell Cook and G. M. McLeod. T. Gastroent. 10(1):64-76, 1967.

A new translucent polyvinyl tube for collecting small intestinal contents and which permits quick positioning in the small intestine and a rapid delivery of the sample to the collecting chamber is described. The tube features only 1 aspiration hole; a distal Hg bag and a large leader balloon which is inflated by a fine vinyl tube cemented to the exterior of the main aspiration tube and an inner balloon controller which is fitted into the main aspiration tube at the site of the aspiration hole. To permit fluoroscopic visualization, the last 10 cm of the main tube are filled with a radio-opaque powder and this is complemented by a radio-opaque stripe on the distal end of the main tube. Each patient was evaluated after an overnight fast. Two collections were generally made on each patient, 1 around the duodenojejunal flexure and the other from the distal jejunum. The first collection is followed by inflation of the terminal balloon and repositioning of the tube for the second collection which is made on the following day. In normal subjects, a total of 28 samples of small intestinal contents were obtained with a total study time ranging from 120-345 min. Total sample wt. in this group ranged from 4-159 g with a sampling wt. rate of 8-202 g/hr. In addition, samples were obtained from patients with mucosal malabsorption (3 patients), pancreatic malabsorption (2), after ileal resection (1) and after gastrectomy (1).

11398 THE PROPHYLACTIC USE OF AN "ELEMENTAL" DIET IN EXPERIMENTAL HEMORRHAGIC SHOCK AND INTESTINAL ISCHEMIA. (E.)

Bounous, G. (McGill-Montreal Gen. Hosp. U. Surg. Clin., Canada), G. Sutherland, A. H. McArdle and F. N. Gurd. Ann. Surg. 166(3):312-343, 1967.

Diffuse necrosis of the intestinal epithelium is confirmed as a primary lesion in hemorrhagic shock; a similar necrosis induced by short-term clamping of the mesenteric arteries is associated with the development of lesions in kidneys, heart and other organs similar to those observed after hemorrhagic shock. The very function of digestion of normal food seems to create in the intestinal mucosa a condition of relative intolerance to ischemia. Both hemorrhagic shock and mesenteric arterial occlusion were induced in a series of dogs. One group was fed a control diet consisting of one 15-ounce can/day of a standard commercial dog food; an elemental ration was prepared to be precisely equivalent in composition and quantity to the control, not only in protein equivalent, fat and carbohydrate, but also in vitamins and minerals; the elemental diet was blended from the following ingredients: aminosol, 500 ml; sucrose, 20 g; lipomul, 20 ml; NaCl, 1.7 g; $KHCO_3$, 1.0 g; vitamins, 5 g; and $CaCl_2$.2 2 g; this diet corresponded to the following values, expressed as g/day (500 ml), with the source of each moiety shown in brackets: prote 25 (aminosol); carbohydrate, 25 (aminosol); carb hydrate, 20 (sucrose); fat, 13.7 (lipomul), Na, 0.1,(aminosol); Na, 0.674 (NaCl); K, 0.33 (amin sol) K, 0.47 ($KHCO_3$); Cl, 1.0 (NaCl); and Ca, 0 ($CaCl_2 \cdot 2\ H_2O$). Feeding of this elemental diet before injury reduced the intracellular digesti burden of the intestinal epithelium, while main taining absorption and nutrition. Some signifi changes occurred in the metabolism of the epithelial cells. A 3-day period on the diet led an increased rate of incorporation of labeled adenine into the ATP of the mucosa. After shoc this rate of incorporation fell proportionally both groups of animals, but the resultant rate the mucosa of dogs on the elemental diet mainta a level 5-fold that reached by dogs on normal f It is concluded that a period of 3 days on the elemental diet not only reduced the intralumina toxic factors, but also appeared to enhance the metabolic state of the intestinal mucosa, makin it more tolerant to ischemia. In proportion to the degree of mucosal integrity, whether morpho logic or metabolic, survival was improved and the extraintestinal lesions were virtually elim ated.

11399 NEW LONG INTESTINAL TUBE FOR RAPID NONOPERATIVE INTUBATION. A PRELIMINA REPORT. (E.)

Edlich, R. F. (U. Minnesota, Minneapolis), E. Gedgaudas, A. S. Leonard and O. H. Wangensteen. Arch. Surg. (Chicago) 95(3) 443-450, 1967.

A new tube for rapid nonoperative intubation is described in which an air-controlled flexible directional tip has been incorporated into the long coiled-spring tube; addition of this flexi tip has facilitated rapid pyloric and jejunal intubation under fluoroscopic visualization, ev in the presence of marked intestinal distention Over a 3-yr. period, 48% of intubations with th long coiled spring intestinal tube were unsuccessful because the tip remained coiled in the stomach; jejunal intubation was achieved in les than 30 min. in 15 of 29 cases. Addition of th controllable tip to the end of the tube enabled pyloric and jejunal intubation to be achieved within 30 min in 29 of 31 patients with intestinal obstruction; 25 of 29 patients successfully intubated were rapidly decompressed by th long tube in less than 48 hr. Successful decompression was not always associated with reli of obstruction. All 5 patients with paralytic ileus had obstructions relent without surgical intervention, compared to only 2 of 18 patients with carcinomatosis. Development of this techn for rapid jejunal intubation had allowed approx 40% more patients with intestinal obstruction t gain the benefits of rapid nonoperative decompr sion.

0 ANGIOGRAPHY IN EXPERIMENTAL STRANGULATING
OBSTRUCTION OF THE SMALL INTESTINE IN
. (E.) Aakhus, T. (Ulleval Hosp., Oslo).
Radiol. [Diagn.] (Stockholm) 6(4):337-347,
.

rel dogs were divided into 4 groups and
ected to the following procedures, using an
0 cm long intestinal loop close to the trans-
n of the lower quarter of the small intestine:
ntestinal strangulating obstruction, 4 dogs;
egmental venous ligature, 3 dogs; 3) ligature
he superior mesenteric vein, 1 dog; and 4)
rol operation (no ligature applied), 1 dog.
ctive superior mesenteric angiography, using
rial exposure technic, was performed pre-
atively and at intervals during the post-
ative period. After the first procedure,
gs had increasing arterial obstruction at
level of the ligature, and in 2 of these,
nation of the contrast medium was noted in
arteries immediately proximal to the point
ompression; blood flow was distinctly reduced
he strangulated area, and this flow reduction
lted in a delayed and prolonged outlining of
arteries, a poor filling of finer arterial
ches and only a slight parenchymatous contrast
ity in the strangulated loop. Arterial flow
the affected area was reduced in all 3 ex-
ments on segmental venous ligature; a char-
ristic delayed and prolonged outlining of
arteries, as well as poor filling of the finer
ches and reduced parenchymatous density in the
cted loop, were clearly demonstrated. Pro-
sive generalized narrowing of the entire sup-
mesenteric artery and its intestinal branches
red in later stages in dogs subjected to the
2 procedures. After ligature of the superior
teric vein, a slight arterial flow reduction
bserved in the corresponding region at 30
postoperatively; no changes from the pre-
tive angiography, apart from derangement of
rteries after manipulation of the intestine,
observed in later stages of this experiment,
fter the control operation. A rapid decrease
stemic blood pressure followed the second
dure, and a slower fall was noted after the
procedure; after the third procedure, there
ome reduction in blood pressure at 8 hr. and
finite fall in pressure occurred after the
ol operation. It is suggested that selective
ior mesenteric angiography may be of diag-
c value in human patients with possible
tinal strangulating obstruction.

INTESTINAL OBSTRUCTION AND SIMILAR
CONDITIONS IN EARLY CHILDHOOD. (Ger.)
, A. (Postgrad. Med. Inst., Prague).
chr. Roentgenstr. 99:1-72, 1967.

osis of the various forms of ileus, based
re than 300 cases of mechanical and functional
uction in the very young, is presented with
y every type of complete or partial ob-
tion included. Obstruction was more fre-
in females than males; the incidence of
mechanical obstruction was greater than the functional in the first 6 days of life; from the second wk. through the fifteenth mo. functional ileus was much more frequent; from the third through the sixth mo. of age no case of mechanical obstruction occurred in over 300 patients. Beginning with the eighteenth mo., frequency of mechanical and functional ileus was the same. The indications provided by contrast medium must be considered with caution. The p.o. admin. of contrast material is strongly contraindicated for all cases of high obstruction; gastric emptying is delayed in complete and partial intestinal obstruction for periods sometimes in excess of 24 hr., thus reducing the usefulness of the contrast material. The position of the contrast material is taken as the X-ray sign of obstruction; this is a specific indication in some diseased states only, e.g., meconium ileus and aganglionosis. Intestinal stenosis can be located by radiologic examination using contrast medium. A fully air-free intestine occurs only when the newborn has not swallowed any air, in stillbirths, and in instances of esophageal atresia. Vomiting, dehydration and severe pneumopathies can cause shrinkage of the air vol.; however, a gas-free intestine never results. During complete or partial obstruction, indications of stasis occur: the normal gas bubbles increase in size; square bubbles form and enlarge into a continuous air-space in the small or large intestine. It is advisable to identify gas in the rectum, sigmoid, and descending colon; this aids in differentiation of the intestinal regions, it also indicates that the obstruction is of recent origin. The presence of gas must be established as being in the small or large intestine; when located in the small intestine, the possibility of mechanical obstruction exists. If the gas is in the large intestine, and the previous evacuation was normal, then a functional type of ileus must be considered. Oral intubation for the introduction of air was seldom used; the best method was the use of a drink such as tea and milk; with 30 ml of fluid 60-70 ml of air was swallowed; with no local hindrance the air was rapidly passed into the small intestine. Air proved to be better than unphysiologic contrast material. When necessary air could be introduced rectally to differentiate the large and small intestine.

11402 RESULTS OF TREATMENT OF INTESTINAL
OBSTRUCTION IN THE NEWBORN AND CHILDREN.
(Ger.) Joppich, I. (U. Clin. Heidelberg, Germany)
and W. C. Hecker. Chirurg 38(7):293-295, 1967.

Intestinal obstruction of widely divergent etiologies such as tumor, atresia, ascariasis, and hernia, was treated surgically in 452 cases with a mortality of 11.8%; 76 were newborn (mortality 28.9%), 296 were from 4 wk. to 4 yr. old (mortality 6.8%), and 80 were from 4-15 yr. old (mortality 13.5%). Hernia was the greatest single cause of intestinal obstruction with 232 cases (51.3%). The high mortality in early infancy was attributed to associated abnormalities, faulty development, prematurity and peritonitis. Of 14 premature infants 5 died but 5 of 14 fullterm newborns also died; all of the latter had peritonitis. In late infancy and childhood mortality was mainly due to inadequate fluid and electrolyte replacement; H_2O and salt deficit may have been severe enough to cause circulatory stasis; a 4-yr.-old patient received a fluid vol. of 4400 ml in 24 hr. (25% of the vol. in the first 3 hr.) in order to stabilize the circulation and to compensate for the H_2O and salt deficiency. Adequate fluid and electrolyte balance resulted in a decrease in mortality from 17% to 1% for children from 4 wk. to 15 yr. old.

11403 DIGESTIVE TRACT OCCLUSION AS A POSTOPERATIVE COMPLICATION IN THE GYNECOLOGICAL AND OBSTETRIC PRACTICE. (Pol.) Higier, J. (2nd Cent. Hosp. Clin., Warsaw). Wiad. Lek. 19(23):1855-1860, 1966.

In 2725 gynecological laparotomies performed between 1946-1963 there were 18 cases of severe postoperative ileus requiring relaparotomy. Ten of the occlusions were due to adhesion of loops of the small intestine, 2 were pure paralytic occlusions (ileus), 2 mechanical occlusions of the large intestine and the remainder were due to intestinal suppuration or peritonitis. Early postoperative ileus was most often seen after cesarean section (8 of 18 cases). There were 2 cases after extrauterine pregnancy, 3 after myoma, 2 after inflammation of the appendages, and 4 after correction of the uterine position. Appendectomy performed during gynecological laparotomy did not cause an increase in these complications. Between 1946-1954 the number of postoperative occlusions amounted to 1.9% of all gynecological laparotomies (11 of 586) while between 1955-1963 there was a reduction to 0.3% (7 of 2139). This reduction was due mainly to improved surgical technics, avoidance of trauma to the intestine with tampons, and so on (by the use of appropriate anesthesia which calms the abdominal cavity), careful peritonealization, and postoperative electrolyte adjustment.

11404 PNEUMATOSIS CYSTOIDES INTESTINALIS IN INFANTS. (Pol.) Grygielowa, S. (Korczaka Hosp., Lodz, Poland) and Z. Tomczyk. Przegl. Lek. 23(4):392-394, 1967.

Analysis of postmortem examinations performed between 1958 and 1964 on 308 children whose deaths were caused by severe diarrhea revealed 9 cases of pneumatosis cystoides intestinalis (2.9% of cases). All were young infants; most were less than 3 mo. old, the oldest being 7 mo. When hospitalized they were in poor general condition, underweight, with severe diarrhea, often marasmic, and with pneumonia and otitis. The cysts were most often found in the large intestine but in 1 case they were present in the small intestine also. It seems that a certain period of time has to elapse before the characteristic changes occur
(approx. 1 mo. after onset of the symptoms) bec
in the infants who died only a few days after t
onset of diarrhea, pneumatosis cystoides intestinalis was not discovered. A certain periodic
of the disease was noted: in 1958 there were 4
cases observed, 1 case in 1959, 1961 and 1963,
2 cases in 1964. It is concluded that this con-
dition is not as rare as it seems to be from th
literature and that because of the absence of a
characteristic clinical picture, an in vivo
diagnosis is extremely difficult.

11405 EXPERIMENTAL INVESTIGATIONS ON POSSI-
BILITIES OF IMPROVEMENT OF THE INTEST
RESORPTION AFTER EXTENSIVE RESECTION OF THE SMA
INTESTINE IN DOGS BY MEANS OF REVERSED, INTESTI
SEGMENTS. (Pol.) Sadowdki, J. (2nd Surg. Clin
Warsaw). Pol. Przegl. Chir. 38(10):1073-1077,
1966.

To study the effect of inserting a reverse peri
staltic segment, after massive resection of the
small intestine, on body wt. and absorption of
fat, protein and carbohydrates, 10 dogs were
divided into 2 groups. In the first group 66%-
75% of the proximal part of the small intestine
was resected; this caused loose stools, diarrhe
a wt. loss of 22-31% and a 7-15% decrease of fa
absorption depending upon the diet. Protein
absorption decreased 4% with standard and 21%
with high-fat diet. After 2-3 mo. a reverse
intestinal insertion was applied and 4-5 mo. la
the initial wt. was regained or surpassed, H_2O
content of stools and absorption of fat and pro
tein returned to normal. In the second group o
dogs the distal part of the small intestine was
resected and the reverse peristaltic insertion
applied simultaneously. These dogs regained th
initial body wt. in 4 wk. and the absorption of
fats and protein and H_2O content of stools was
the same before and after the operation. There
were no complications after the insertion of th
reversed segment and radiology revealed no distention of the gastrointestinal tract. There
no difference seen when the proximal or distal
part of the small intestine was resected.

39 TREATMENT OF PERFORATED PYLORIC ULCER BY A MODIFICATION OF THE NEUMANN NET

F. (Ger.) Smolinski, E. (U. Clin., Rostock,
many). Zbl. Chir. 91(48):1799-1801, 1966.

2 yr., 12 patients (8 of them elderly) were gically treated for perforated pyloric ulcer hout mortality using a Kehr T-drain to carry gastric secretion into the duodenum without hing the ulcer, and using a modified net cuff ised by Neumann. The location of the perforated mach lesion (usually on the anterior pyloric l) and the general condition (often including nosis of the pylorus) predicated palliative gery. The T-drain was used with the longer (4-5 cm) placed so that it extended into duodenum and the shorter arm into prepyloric ion of the stomach. The third arm was passed ough the perforation of the ulcer and fastened a waterproof closure using tied sutures or a se-string suture; the net around the third , anchored in the stomach wall, and fastened he parietal wall of the abdomen, secured the rain in an opening of the body wall; this wed drainage of the stomach and also the ly of liquid, nutrients and electrolytes to patient. The removal of the drain and the cuff presented no difficulties 4 mo. later gastric resection. After recovery from the t operation and prior to the second the ent was ambulatory, the tube in the body wall ng been clamped off.

40 RESIDUAL GASTRIC CONTENTS AFTER VAGOTOMY, GASTRECTOMY AND SUTURE OF PERFORATED IC ULCER.

(Pol.) Tołłoczko, T. (First Surg.
., Acad. Med., Warsaw, Poland) and M. Szostek.
Przegl. Chir. 38(12):1436-1439, 1966.

residual gastric content was measured for 3 in 105 patients who underwent the following s of surgery: 30 gastrectomies with subhragmatic vagotomy for duodenal ulcer, 30 rectomies without vagotomy for duodenal ulcer, astrectomies for gastric ulcer and 15 sutures erforated duodenal ulcer. In all cases of rectomy and gastrectomy with vagotomy the values of residual gastric contents were est on the second postoperative day. In ents with suture of perforated duodenal ulcer e was a slightly gradual, but statistically gnificant, increase of residual contents for 3-day period. Vagotomy had no influence on amount of residual gastric content.

1 MANOMETRIC STUDY OF THE EFFECT OF VAGOTOMY ON THE GASTROESOPHAGEAL NCTER.

(E.) Crispin, J. S. (Winnipeg Gen.
., Manitoba, Canada) and J. F. Lind. Canad.
urg. 10(3):299-303, 1967.

effect of therapeutic transabdominal vagotomy ne functional integrity of the gastroesophageal sphincter both at rest and during abdominal compression in 10 patients (28-75 yr.) with chronic, intractable peptic ulcer and without demonstrable esophageal disease or hiatal hernia is described. Motility studies were carried out from 1 wk. to 1 yr. after truncal vagotomy (9 pyloroplasties and 1 gastrojejunostomy) and the results were compared with preoperative results. Postoperatively, no patient demonstrated any sign of hiatal hernia and the length and relationship of the sphincter to the level of the diaphragm, mean max. sphincteric pressure, and the stomach-to-sphincter gradient did not change significantly from the preoperative values. Postoperative results associated with abdominal compression showed a sphincter pressure which was significantly reduced (from 15.5 to 5.8); this, in turn, yielded a significantly reduced stomach-to-sphincter gradient also (from 20.1 to 7.1). Pressure increase in the stomach postoperatively approx. that observed preoperatively. Intraesophageal pressure gradients remained essentially unchanged postoperatively. The reduction in sphincteric pressure postoperatively may be the result of transsection of the afferent limb of the vagal reflex arc during vagotomy.

11442 BOWEL HABIT AFTER GASTRIC SURGERY.

(E.) Nelson, P. G. (Roy. Melbourne Hosp.,
Australia). Med. J. Aust. 1(25):1242-1245, 1967.

By direct personal interview a comparable blind study with statistical analysis was made comparing the bowel habit of patients after 4 standard operations for duodenal ulcer. A total of 205 patients were interviewed between 1-6 yr. after operation; 49 had a standard Polya resection, 46 had vagotomy and antrectomy, 61 pyloroplasty and vagotomy and 49 had vagotomy and gastroenterostomy. Aberrations of bowel habit were seen in 25-35% of patients after vagotomy, but severe disability was not common. The associated gastric operation had no effect on the incidence of bowel aberration after vagotomy. A statistically lower, but appreciable, incidence of aberrations followed gastrectomy. There is no ready explanation for the less satisfactory postoperative bowel habit after vagotomy. Little clinical or experimental support is found for the hypothesis that selective vagotomy rather than total section confers significant improvements in bowel habit. The case for selective vagotomy in operations for duodenal ulcer may rest not on the improvement in postoperative bowel habit, but on other, less well-studied, extragastric effects of total vagal section.

11443 GASTRIC OR DUODENAL ULCER IN PATIENTS WITH COEXISTENT ATHEROSCLEROSIS.

(Pol.) Hirnlowa, L. (3rd Intern. Dis. Clin., Wroclaw,
Poland), K. Janicka and M. Dyczkowska. Pol. Tyg.
Lek. 22(12):435-437, 1967.

Coexistence with atherosclerosis was observed in 40 of 260 cases of gastric and duodenal ulcers. A detailed clinical, biochemical and radiological comparison was made of these 50-80-yr.-old patients (Group 1) with forty 25-53-yr.-old patients without coexistent atherosclerosis (Group 2). Gastric or duodenal ulcer was of shorter duration among patients with atherosclerosis (no more than 7 yr. duration) than in the control group (up to 25 yr.). In 26 patients of Group 1 there was bleeding from the digestive tract (as compared to 14 in the control group) occurring more frequently and without warning symptoms. In this same group there was a lack of the periodic and seasonal aggravation of symptoms, pain was not connected with the time of eating and no pain occurred during the night and when fasting. There was normal or decreased acidity of gastric contents (moderate hyperacidity, free HCl 40%-60%, was noticed only in 14 patients as compared to 27 in the control group). Roentgenologic examinations revealed 18 gastric and 17 duodenal ulcers in Group 1, while Group 2 had 9 gastric and 25 duodenal ulcers. Group 1 responded much more slowly to therapy with alleviation of the symptoms 4-16 wk. after initiation of treatment, while Group 2 showed improvement in 2-3 wk. It is concluded that all these differences may indicate a different etiology of peptic ulcers in these 2 groups.

11444 CARBOHYDRATE METABOLISM IN DUODENAL ULCER PATIENTS. (E.)

Buchanan, K. D. (Roy. Infirm., Glasgow, Scotland), M. T. McKiddie, A. C. Lindsay and W. G. Manderson. Gut 8(4):325-331, 1967.

Since abnormalities of carbohydrate metabolism have been reported to occur in association with peptic ulceration, p.o. and i.v. glucose tolerance tests were performed in 14 patients (all men; 15-38 yr. old; all had radiological evidence of duodenal ulceration without delayed gastric emptying; none were more than 10% above ideal body wt., and several were under weight) with duodenal ulceration and in 14 control subjects (all men; 20-31 yr. old; all were within 10% of ideal body wt. and none had a family history of diabetes mellitus). Plasma insulin levels were measured by immunoassay. Blood sugar levels after p.o. glucose were similar in the 2 groups, but plasma insulin levels were significantly higher in ulcer patients. The i.v. glucose tolerance tests produced almost identical blood sugar and plasma insulin levels in both groups. In duodenal ulcer patients, no correlation was found between the insulin response to p.o. glucose and the gastric secretion after an augmented histamine test.

11445 A THERAPEUTIC TEST FOR DIFFERENTIAL DIAGNOSIS BETWEEN GASTRIC ULCER AND ULCER MALIGNANT DEGENERATION. (Rus.)

Simbirtseva, L. P. (Inst. Oncol., Leningrad, USSR) and M. L. Gershanovich. Vop. Onkol. 13(3):24-29, 1967.

In 25 patients (14 males, 11 females; age 32-70
yr.) with gastric ulcers of benign or malignant
nature the use of 4-methyluracil (up to 3 g/day
in 3-6 admin.; total up to 100 g; p.o.) for a
therapeutic test in differential diagnosis coul
be helpful. Of 16 patients with diagnosis of
benign gastric ulcers (on first X-ray examinati
4-methyluracil treatment in 13 resulted in the
disappearance of X-ray symptoms of niche and
inflammatory changes with no recurrence 6-14 mo
later, in 1, the niche remained unchanged and i
flammatory symptoms regressed and the ulcer la
healed. In 1, the niche disappeared but gastri
wall infiltration remained; however, surgery
showed benign leiomyoma of the prepyloric part;
in 1, treatment was not accompanied with roentg
logic improvement and surgery verified diagnosi
of malignant degeneration of gastric ulcer. I
4 of 7 patients with possible malignant degene
tion of ulcer, treatment resulted in disappeara
of the niche and the benign nature of the ulce
was established subsequently during prolonged
observation. In 1, despite positive test resu
possible malignant degeneration was not elimin
however, surgery showed a healed ulcer. In 2
persons 4-methyluracil did not induce ulcer he
and surgery revealed a malignant process (mali
degeneration of the ulcer and low-differentiat
carcinoma in situ with superficial erosion).
2 patients with diagnosis of the ulcerative fo
of gastric cancer, therapy caused no disappear
of the niche and surgery revealed the ulcerati
form of adenocarcinoma and malignant degenerat
of the gastric ulcer. The therapeutic effect
4-methyluracil in peptic ulcer is also stresse

11446 DEVELOPMENT OF PEPTIC ULCER IN WORKE
EXPOSED TO CARBON DISULFIDE. (Pol.)

Andruszcak, K. (Wročlaw Inst. Synthetic Fibers
Poland). Med. Pracy 17(6):555-560, 1966.

A greater incidence of ulcers was found among
workers exposed to CS_2 in a viscose-producing
factory than among nonexposed employees. The
study included 1453 men and 905 women between
18-65 yr. old and extended over a 4-yr. perio
Among the 524 men and 64 women who were const
exposed to the action of CS_2 there were 53 ca
(9%), (49 of the 524 men, 9.3% and 4 of the 6
women, 6.2%) who suffered from ulcers (28 duo
16 gastric and 9 of changing location). Of 9
men and 841 women in the control group there
52 cases (2.9%) of ulcer patients (36 men, 3.
and 16 women, 1.9%). The difference between
2 groups was statistically valid. The diseas
most often observed in those 28-38 yr.old and

47 A STUDY OF PSYCHOLOGICAL FACTORS IN PATIENTS WITH SURGICALLY INTRACTABLE DENAL ULCER AND THOSE WITH OTHER INTRACTABLE ORDERS. (E.) Thoroughman, J. C. (VA Hosp., anta, Ga.), G. R. Pascal, J. R. Jarvis and C. Crutcher. Psychosom. Med. 29(3):273-278, 7.

s study shows that the psychological measures ch had been used, with an excellent predictive idity in a previous study, to separate poor gical results from good surgical results in ients with intractable duodenal ulcers were specific to such a condition, but occur with er intractable illnesses. When 20 patients n intractable duodenal ulcers who gave poor gical results were matched with 20 patients n other intractable disorders such as chronic back pain, rheumatoid arthritis etc., and n were subjected to the Deprivation Scale lysis no particular item differentiated the roups. Studies of the early parental behavior ing the patient's first 10 yr. again did not ferentiate the 2 groups. Furthermore, these roups could not be separated on complaints ut ingestion, sleep and motility. These data gest that patients who have had environmental overishment and poor early relationships with ents belong to a much larger population of avioral deviants rather than a population with pecific physiological propensity.

48 SC-15396: A NEW ANTIULCER COMPOUND POSSESSING ANTI-GASTRIN ACTIVITY. (E.) k, D. L. (G. D. Searle & Co., Chicago, Ill.) R. G. Bianchi. Life Sci. 6(13):1381-1387, 7.

i.v. admin. of 2-phenyl-2-(2-pyridyl)-thio- camide (2-10 mg), a nonanticholinergic, anti- er compound, to rats during gastric perfusion duced a reversible inhibition of gastrin (0.1- μg) stimulation. In mongrel dogs with chronic tric fistulas or dogs with gastric pouches, n innervated (Pavlov) and denervated (Heiden- n), gastric secretion was stimulated with tamine diphosphate (0.05 mg/kg, admin. s.c.), C-terminal gastrin tetrapeptide (100 μg, admin. .) and food (25 g of canned salmon). The anti- er compound was admin. p.o. in doses of 10, or 50 mg/kg at 30 min. before the gastric mulant. The antiulcer compound produced a ked inhibition of gastrin tetrapeptide-stimulated retion, but inhibition of gastric secretion mulated by food was equivocal and histamine mulation was not significantly affected. It concluded that this new nonanticholinergic, iulcer compound is a specific inhibitor of trin-induced gastric secretion.

49 EFFECT OF CHLORDIAZEPOXIDE ON STOMACH ULCERS IN RABBIT INDUCED BY STRESS.) Dasgupta, S. R. (Calcutta U., India) and P. Mukherjee. Nature (London) 215(5106):1183, 7.

Male rabbits were subjected to emotional stress in the form of electroshock daily for 21 days; 3 rabbits received daily i.p. inj. of chlordiazepoxide (50 mg/kg) 30 min. before electroshock, and controls received electroshock alone. Stomachs from controls all showed extensive congestion, numerous hemorrhages, shedding of epithelium over large areas and distinct ulceration; among those that received chlordiazepoxide there was slight shedding of epithelium in 1 animal, and some congestion in all of them, but no ulceration and no hemorrhage. It seems that premedication with chlordiazepoxide affords protection against the effects on stomach of emotional stress. If it is assumed that stomach lesions after emotional stress are due to adrenocortical hormone released in response to increased conc. of ACTH in the blood, it can be inferred (on the basis of the results described herein) that the antagonism between chlordiazepoxide and ACTH prevents the release of adrenocortical hormones in amounts sufficient to damage the stomach.

11450 DEGRADED AND UNDEGRADED CARRAGEENANS AND EXPERIMENTAL GASTRIC AND DUODENAL ULCERATION. (E.) Anderson, W. (U. Strathclyde, Glasgow) and P. D. Soman. J. Pharm. Pharmacol. 19(8):520-526, 1967.

The prevention of histamine-induced gastric and duodenal ulceration in the guinea pig was examined using a series of undegraded and degraded carrageenans. Histamine acid phosphate (10 mg/kg), suspended in a beeswax-arachis oil (10:90) base (1 mg/ml), was admin. i.m. to intact fasted guinea pigs. This treatment consistently produced duodenal ulceration at the end of 24 hr.; carrageenan was admin. in drinking water in a total dose of 115-2400 mg. Gastric ulceration was produced in the pylorus-ligated guinea pig; saline (1 ml) alone (control) or containing half the dose of carrageenan in soln. was inj. intraduodenally 30 min. before, and repeated immediately after, inj. of histamine acid phosphate (5 mg/kg, s.c. in saline, 1 ml/kg). Total dose of carrageenan, admin. intraduodenally, ranged from 20-400 mg. Undegraded carrageenans were active at lower doses than degraded carrageenans; the high viscosity of the undegraded carrageenans in soln. prevented their use in larger doses. Degradation of carrageenan without serious loss of sulfate, gives a product which allows the dose to be increased to a degree that its effect more than offsets the slight loss in activity caused by the degradation. No single feature of carrageenan structure could be related to anti-ulcer activity, although degradation, and hence reduction of molecular size, generally reduced activity. Sulfate contents over 30% had little apparent effect on activity; κ-carrageenans were not consistently different in anti-ulcer activity from λ-carrageenans. This contrasted with the antipeptic activity of carrageenans, where κ-carrageenans were less active than their λ-counterparts. As with antipeptic activity, the degree of anti-ulcer activity was probably determined by a combination of structural features which included molecular size and polyanionic properties.

11451 ON THE PROBLEM OF GASTRIC ULCER FORMATION BY GLUCOCORTICOIDS IN RATS AND THE EFFECT OF ANDROGENIC-ANABOLIC STEROID ON THEM. (E.) Linèt, O. (Res. Inst. Natural Drugs, Prague) and J. Mikulášková. Endokrinologie 51(3-4):224-233, 1967.

A 4-day regimen of either prednisolone or its acetate (5 mg/day/rat increased to 15/mg/day/rat) in fasting rats resulted in only hemorrhages of the gastric mucosa. In further studies, after admin. of hydrocortisone acetate (10 mg/day/rat), a series of mucosal alterations resulted. Most common were the punctiform hemorrhages which represented either a superficial mucosal necrosis with both grossly dilated vessels and hemorrhage at the base of the lesion or a superficial mucosal lesion with a pronounced WBC line of delineation at the base of the lesion along with gross edema of the submucosa. Lesions greater than 1.5 by 1.5 mm showed mucosal defects extending to varying depths. The most severe grade observed consisted of hemorrhagic necrosis of the whole gastric wall along with concomitant thrombosis of the gastric blood vessels. Simultaneous admin. of hydrocortisone and androgenic-anabolic drugs (19-nortestosterone phenylpropionate, methandienone and dimethylandrostanolone) resulted in an apparent increase in the number of macroscopically visible lesions. Dimethylandrostanolone decreased the number of hemorrhages, however. Combined drug admin. also failed to reverse the marked wt. loss associated with hydrocortisone alone.

11452 GASTRIC ULCERATION IN TUMOR-BEARING RATS. (E.) Baillie, P. (NCI, Bethesda, Md.), F. K. Millar, S. D. Morrison and A. W. Pratt. J. Nat. Cancer Inst. 38(6):939-946, 1967.

Adult, male Sprague-Dawley albino rats, in which the Walker carcinosarcoma 256 (1 of 2 lines) was transplanted, were fed ad libitum 1 of several diets (diluted evaporated milk, chow, dried tumor base, casein base), or were fed a restricted amount of the casein diet; these rats were then examined for gastric ulceration. Normal (nontumor-bearing) rats were fed ad libitum or were partially or totally deprived of food. In tumor-bearing rats fed ad libitum, ulcers developed in both the forestomach and in the glandular area of the stomach 21 or more days after tumor transplant with all diets fed, except chow. Ulcer incidence increased with age of the tumor, but there was great variability. In tumor-bearing rats partially deprived of food and killed 18 days after transplant, the ulcer incidence was significantly lower than in rats with spontaneous comparable intake killed 28 days after transplant. In normal rats totally deprived of food, the incidence of forestomach ulcers increased with the period of deprivation (3-7 days); glandular ulcers developed only after more than 6 days of deprivation. Fro the relation of ulcer incidence to tumor wt., food intake, adrenal wt., and carcass wt. change it appeared that gastric ulceration in the tumor bearer required a degree of food deficit, such a occurs with progressive tumor growth, in conjunction with some minimal stage of tumor developmen No definitive cause for ulceration was found.

11453 CELL PROLIFERATION DURING THE DEVELOPM OF STRESS EROSIONS IN MOUSE STOMACH. (E.) Kim, Y. S. (Cornell U. Med. Coll., New York, N. Y.), R. Kerr and M. Lipkin. Nature (London) 215(5106):1180-1181, 1967.

The number of cells incorporating tritiated thym dine (25 µc/mouse, specific activity 6.7 c/mmole and entering into mitosis in the stomach of the (male CFW) mouse during prolonged stress (restraint), before and during the development of erosions was measured. Histological examination of the gastric mucosa revealed scattered focal areas containing moderate vacuolization of cytoplasm in epithelial cells and slight-to-moderate decrease in periodic acid-Schiff-positive mucopolysaccharide; desquamation of surface cells wa increased, and in a few areas early collapse of the mucosa was noted, the cells having abnormal eosinophilic cytoplasm with pyknotic nuclei; there was no edema, necrosis or inflammatory exudate. Eleven of 13 animals that had been unc stress had reduced mitoses compared with control and 12 of 13 had reductions in labeled cells. The frequencies of mitoses and labeled cells were significantly decreased in the stress group these decreases were in areas of mucosa containi no histological alterations mentioned earlier; despite cell damage and loss, therefore, during the development of erosions the rate of replacement of epithelial cells was significantly lower than that of the nonstressed controls. Tritiate L-leucine-4,5 (specific activity 5 c/mmole, 100 µc/mouse) was also inj. i.p. into 2 additior groups of stressed and control animals maintaine under the same conditions, and the animals were also sacrificed 1 hr. after inj.; comparative rates of protein synthesis in intestinal epithel cells were estimated. The results showed active incorporation of leucine into all cell types. Throughout the mucosa, epithelial cells showing histological abnormalities were well-labeled wit leucine, as observed after early radiation damag

11454 EMOTIONAL REACTIVITY AND SUSCEPTIBILIT TO GASTRIC EROSIONS. (E.) Ader, R. (U. Rochester Sch. Med. Dent., N. Y.). Psychol. Rep. 20(3):1188-1190, 1967.

Data from experiments using Charles River rats or rats from a genetically heterogeneous background were re-analyzed; the animals were depriv of food and water for 18 hr. before a 6-hr. peri of immobilization in flexible wire mesh; at leas 2 wk. prior to immobilization, all animals were observed in an open-field and/or a reaction-to-handling test. No evidence for a relationship

tween emotional reactivity and susceptibility
gastric erosions was found. In only 1 instance
s there a significant behavioral difference
tween animals that did and did not develop
osions. Further analysis of the quantitative
asures of behavior yielded by the open-field
ich might have uncovered a curvilinear associa-
on between these behaviors and susceptibility to
osion also did not indicate any relationship.
ese results suggest that the differences observed
another investigator were a concomitant of the
lective breeding and that the behavioral measures
rported to reflect "emotionality" were not gen-
ally related to the subsequent development of
stric erosions.

55 BEHAVIORAL AND PHYSIOLOGICAL RHYTHMS
AND THE DEVELOPMENT OF GASTRIC EROSIONS
THE RAT. (E.) Ader, R. (U. Rochester Sch.
., N. Y.). Psychosom. Med. 29(4):345-353, 1967.

s subjected to a 6-hr. period of immobilization
e more susceptible to the development of gas-
c erosions if the immobilization was imposed
ing the peak rather than the trough of the
mals' 24-hr. activity rhythm. The incidence
erosion was increased in both groups when the
mals were deprived of food 24-hr. prior to
immobilization. Furthermore, in experiments
ng rats housed under a 12-hr. light-dark sched-
, a 24-hr. rhythm in plasma pepsinogen level
noted which synchronized with the 24-hr.
ivity cycle. However, the range of pepsinogen
ues during a 24-hr. period did not exceed 20%
the overall mean so that the difference in
sinogen levels were not sufficient, in them-
ves, to account for the observed differences
susceptibility to gastric erosions. Plasma
ticosterone levels also showed a 24-hr. rhythm
it did not correlate with the activity. More-
r, no relationship was found between plasma
ticosterone levels and the presence of erosions
lowing 6-hr. immobilization.

56 EXPERIMENTAL STUDY OF GASTRIC INTOLERANCE
OF COATED MICROGRAINS OF ASPIRIN. (Fr.)
nat, P. (47 quai de la Tournelle, Paris), P.
ter, J. Fontagné and B. Flouvat. Therapie
2):403-410, 1967.

tric tolerance to aspirin and microencapsulated
irin in rats (180-280 g) was studied by 3
cedures. 1) Ordinary aspirin and coated (with
yl cellulose) aspirin in aqueous gum suspensions
e admin. by esophageal intubation to groups
rats in doses of 250 mg/day, 5 days/wk. for
k. At the end of the experimental period some
s were autopsied and others were kept under
ervation for 3 wk. prior to autopsy. 2) The
mals were fasted for 4 days during which they
eived 25, 50, or 100 mg/kg/day of aspirin or
ted aspirin by esophageal intubation; on the
rth day, 5 hr. after the last dosage, the
mals were autopsied. 3) Animals treated accord-
to the second procedure received 50 mg/kg/day; on the fourth day tissue from each stomach was fixed for general histology, in acetone for histochemical demonstration of hydrolases, and in a mixture of acetone and dry ice for hydrolytic and oxidation-reduction enzymes. The degree of ulceration following the first procedure was only about 50% as great with coated aspirin as with the ordinary type. The second procedure showed a reduction of ulceration of about 33% due to microencapsulation. The degree of ulceration increased with increasing dosages of aspirin. The histological effects included venous and capillary congestion, regional dedifferentiation of some epithelial and infundibular cells, punctiform ulcerations frequently covered with a mucofibrinous layer with entangled cellular debris, and larger ulcerations that did not reach the submucosa. Histochemical studies showed a definite inhibition of mucus secretion. The serum levels of aspirin were the same for both types of aspirin when admin. in the same dosages to animals of the same wt.

11457 ENDOGENIC HISTAMINE AND EXPERIMENTAL GASTRIC ULCERS IN THE RAT. (Fr.) Schwartz, J. C. (Fac. Pharm., Paris), R. Boulu and G. Valette. C.R. Soc. Biol. (Paris) 161(1):50-53, 1967.

The action of histamine on the formation of gastric ulcers provoked by constraint, phenylbutazone (100 mg/kg, i.p.), or reserpine (100 mg/kg or 8 mg/kg, i.p.), was studied in 285 white rats (100-140 g). Histamine action was tested with the prior treatment of either 13-20 mg/kg s.c. of aminoguanidine, an inhibitor of diaminoxidase, reducing the degradation of histamine, or 300 mg/kg i.p. of bromo-4-hydroxy-3-benzyloxamine, a specific inhibitor of decarboxylase, blocking the synthesis of histamine. The differences in ulcer incidence between the experimental and control animals (inj. with saline only) were not significant, indicating that ulceration was not modified by a reduction in destruction of histamine in vivo, or by a decrease in the biologic production of the amine.

11458 THE INFLUENCE OF LOCAL DISORDERS OF BLOOD CIRCULATION ON THE DEVELOPMENT OF ULCERS IN THE SMALL INTESTINE IN RATS. (Pol.) Ławinski, M. (Inst. Path. Anat., Wroclaw, Poland) and J. Szacki. Pat. Pol. 18(1):103-110, 1967.

A total of 76 male Wistar rats of 200-250 g wt. and divided into 2 groups were used to determine the effect of the inj. of 0.2 ml of conc. NaCl soln. into the mesentery of the small intestine. Of the first group, 20 rats received 0.2 ml of the following soln.: 15 ml 0.9% NaCl, 4.5 g NaCl, and 3 g of wheat starch (to slow absorption of NaCl). Six rats received the same soln. but with no starch and 20 were used as controls. The second group comprising 30 rats received the same inj. of conc. NaCl but a constriction of the mesenteric vein was induced causing hyperemia of the intestinal wall. In 14 of these animals excessive constriction of the mesenteric vein caused death due to hemorrhagic enteritis within 3 days after the operation. The surviving rats were sacrificed on days 3, 8, 14, and 21 after the inj. and segments of the intestine were examined macro- and microscopically. Ulceration occurred in 50% of the animals of both experimental groups surviving 8-14 days. Hyperemia, induced by constriction of mesenteric vein, had no effect on the frequency of ulcers. Other pathological changes (adhesions, thickening of the mucous membranes and cicatrization of the mesentery) were seen in 27% of rats of the first group and peritoneal adhesions in 13.3% of the second group. Histological examination of the ulcerated tissue showed that they were identical to human ulcers of the small intestine. Since the inj. of conc. NaCl soln. into the mesentery caused local disturbances in blood circulation, it was concluded that such disturbances in the mesentery and intestinal walls in humans may give rise to ulcers.

)9 ULCERATIVE COLITIS AND CROHN'S DISEASE. (Nor.) Gjone, E. (State Hosp., Oslo) Norsk. Laegeforen. 87(9b):908-911, 1967.

erative colitis had an incidence (in three ·. periods beginning with 1946) of 8.6, 15.1 20.6 cases/yr./million population; this in-ase appears to be due to better diagnostic ns. The incidence among men and women is ·ly the same. Except in childhood and persons ve the age of 70 when susceptibility is less, incidence is fairly uniform. The total number cases of regional enteritis was 73 in the period 5-63. In the period 1956-1960, there were 362 es of ulcerative colitis with an incidence of 5 million/yr. For the same period there were cases of regional enteritis with an incidence 2.2 million/yr. This means 1 case of regional eritis is diagnosed for every 9.3 cases of erative colitis.

10 PROGNOSIS AFTER RESECTION OF CHRONIC REGIONAL ILEITIS. (E.) Lennard-Jones, E. (Cent. Middlesex Hosp., London) and G. A. lder. Gut 8(4):332-336, 1967.

ee definitions of recurrence (symptomatic urrence, symptomatic relapse with radiological 'or surgical evidence of recurrent disease, further resection for regional ileitis) e used to calculate by an actuarial method the urrence rate after resection for chronic re-nal ileitis in a series of 78 patients from ospitals. In every patient, the disease af-ted primarily the terminal ileum; the adjacent on was affected in 30, in 3 there was a skip on higher in the ileum and in 4 patients the noid colon was involved by serosal adhesion. low-up was complete in 73 of 78 patients. The imated probabilities in this series showed : after a first resection for regional ileitis, urrent symptoms were likely in approx. 33% the patients within 5 yr. and in slightly more n 50% within 10 yr.; recurrent symptoms with iological and/or surgical evidence of recur-t disease were likely in approx. 25% at 5 yr. approx. 50% at 10 yr. Approx. 17% of the ients could be expected to require further ection within 5 yr. and 25% within 10 yr. The imated mortality rate from regional enteritis er the first resection was 7% at 5 yr. and 12% 10 yr. In a small series of 15 patients the urrence rate after a second resection was more n twice as great as after a first resection. se definitions of recurrence and this method analysis are suggested as a possible basis for ure analyses so that the results of treatment different groups of patients may be compared.

11 REGIONAL ENTERITIS OF THE COLON. DISTINCTIVE FEATURES OF THE ENTITY. (E.) <, W. A. (Cleveland Clin. Found., Ohio), R. B. nbull, Jr. and R. G. Farmer. J.A.M.A. 201(10): -746, 1967.

Of approx. 1500 cases of primary ulcerative disease of the colon seen over a 15-yr. period, approx. half were classified as regional enteritis of the colon. This disorder is grossly characterized by serpiginous or longitudinal furrow ulcers or both, segmentally or diffusely arranged with areas of normal-appearing mucosa separating the ulcers. Microscopically, the inflammation is transmural. Noncaseating, sarcoid granulomas may be found, but are absent in 33% of the cases. Deep fissures, which may extend through the intestinal wall, may be observed in 25%-30% of the cases and appear to be the basis for fistula formation. Postcolectomy ileitis occurs much more commonly in patients with regional enteritis of the colon than in those with chronic ulcerative colitis; the incidence is approx. equal in patients with or without ileitis at the time of first colectomy. Of 151 cases studied in detail, 87 were regional enteritis of the colon (48 granulomatous, 39 nongranulomatous), 48 were chronic ulcerative colitis and 16 were unclassified. The ranges of age distribution of patients having regional enteritis of the colon and chronic ulcerative colitis were 9-75 yr. and 9-70 yr., resp.; a slightly higher percentage of patients with chronic ulcerative colitis (25%) were more than 50 yr. of age as compared to the patients with regional enteritis of the colon (10%). Of 87 with regional enteritis of the colon, 42 had involvement of the terminal portion of the ileum at the time of colectomy, compared to only 5 of 48 with chronic ulcerative colitis. Of those with regional enteritis of the colon, the rectum was normal in 40% as compared with 9% of those with chronic ulcerative colitis. There was no carcinoma arising in the intestine among those with regional enteritis of the colon; this contrasted with 6 (12.5%) of 48 with chronic ulcerative colitis who developed carcinoma. There were 18 deaths in the 151 cases; 10 were in the chronic ulcerative colitis group and 7 in the group with regional enteritis of the colon. Toxic dilatation of the colon occurred in 13 of 48 patients with chronic ulcerative colitis, and in 12 of 87 patients with regional enteritis of the colon. Pyoderma gangrenosum and arthritis were noted occasionally in association with both regional enteritis of the colon and chronic ulcerative colitis, but most often with the latter. After colectomy, there was a 92% cure in those with regional enteritis of the colon and an 80% cure in those with chronic ulcerative colitis. Of the 16 cases of unclassified colitis, 6 patients probably had some form of regional enteritis of the colon and 1 patient probably had chronic ulcerative colitis; the other 9 patients did not show sufficient specific changes for definitive diagnosis.

11512 PSYCHIATRIC ASPECTS OF REGIONAL ENTERITIS. (E.) Parfitt, H. L. (U. Hosp., Edmonton, Alberta, Canada). Canad. Med. Ass. J. 97(13):807-811, 1967.

11513 COMPARISON OF VENOUS AND CAPILLARY BLOOD SAMPLES IN LACTOSE TOLERANCE TESTING. (E.) McGill, D. B. (Mayo Clin., Rochester, Minn.) and A. D. Newcomer. Gastroenterology 53(3):371-374, 1967.

Lactose tolerance tests were performed on 22 normal subjects (13 men, 9 women; all Caucasian; 21-57 yr. old, with a mean age of 33 yr.), and on 10 patients (6 men, 4 women; 25-58 yr. old, with a mean age of 38 yr.) with lactase deficiency (less than 0.5 U of lactase/g of wet wt. of jejunal mucosa); blood for glucose analysis was drawn simultaneously from a vein in the arm and a finger tip of the opposite extremity. The mean peak increase of glucose in capillary blood in 21 of 22 normal subjects was 44.2 mg (20-99 mg/100 ml), while in venous blood it was 30.8 mg (7-62 mg/100 ml). The 4 subjects who had a peak increase of less than 20 mg% glucose in venous blood and thus had flat curves, had normal curves for capillary blood. In lactase-deficient patients, 8 of 10 capillary peaks were greater than the venous peaks. Three lactase-deficient subjects with flat venous curves had normal capillary curves; 1 subject had low normal peaks for both blood samples. It is concluded that use of capillary blood will eliminate flat curves in normal individuals and that peak rises in blood glucose of more than 20 mg/100 ml will occur in some patients with lactase deficiency. It is also concluded that the 50-g, 60-min. venous lactose tolerance test is useful in detecting lactase deficiency, if both peak rise in blood glucose and development of symptoms are noted.

11514 INTESTINAL DISACCHARIDASES IN TROPICAL SPRUE. (E.) Desai, H. G. (Tata Mem. Hosp., Bombay, India), A. V. Chitre, D. V. Parekh and K. N. Jeejeebhoy. Gastroenterology 53(3): 375-380, 1967.

Disaccharidase activity was measured in the jejunal mucosa obtained by peroral biospy in 22 control subjects (21-62 years old, mean 34), in 12 subjects with chronic gastritis or duodenal ulcer, and 50 adult patients (14-70 yr. old, mean 35 yr.) with tropical sprue. The latter had chronic diarrhea not due to pathogens or specific anatomical lesions of the intestine; 82% had steatorrhea, 76% had ^{58}Co vitamin B_{12} malabsorption, and 48% had D-xylose malabsorption. Each patient had malabsorption of at least 2 of the above test substances, and abnormalities of the jejunal mucosa (surface convolutions or leaves and convolutions) were observed under the dissecting microscope in 62%. In 22 controls, the mean and range of lactase, sucrase and maltase levels in specimens of jejunal mucosa were 14.6 (1.6-33.0) U, 69.0 (17-188) U, and 181.0 (47.0-456) U, resp.; in 12 subjects with gastritis or ulcer, the mean and range of lactase levels in specimens of jejunal mucosa was 10.7 (0-46.0) U. In 50 patients with tropical sprue, the mean and range of lactase, sucrase and maltase levels in jejunal mucosa were 3.3 (0-27.0) U, 45 (0-143) U, and 131 (12-327) U, resp. Lactase was less than 1 U in 64% of the patients. The lactase levels observed in Indian controls were low as compared with those reported from western populations. The patients with tropical sprue had significantly lower lactase values than controls; and sucrase and maltase values were also low in some patients, but not significantly so. No correlation was noted between the dissecting microscopic appearances of jejunal mucosa and disaccharidase levels. After admin. of tetracycline (1 g/day in divided doses) for 2 wk. to 7 patients with tropical sprue, lactase activity increased in only 2 patients, while sucrase increased in 6 patients and maltase increased in 4 of 5 patients studied. In patients with tropical sprue, low lactase levels were found even in those who consumed more than 8 ounces of milk/day, and there was no significant relationship between milk intake and lactase levels.

11515 MODIFICATION IN THE XYLOSE ABSORPTION TEST AS AN INDEX OF INTESTINAL FUNCTION. (E.) Sammons, H. G. (East Birmingham Hosp., England), D. B. Morgan, A. C. Frazer, R. D. Montgomery, W. M. Philip and M. J. Phillips Gut 8(4):348-353, 1967.

Xylose excretion in the urine after doses ranging from 0.5-25 g was determined in normal subjects and patients (44) with enteropathy; the 2-hr. and 5-hr. excretion and the 2:5 hr. excretion ratio was determined. All of the enteropath patients had a serum urea level less than 50 mg% and no proteinuria; 4 had gluten-induced enteropathy affecting the upper small intestine with marked steatorrhea; 4 others had steatorrhea but a completely normal absorption of xylose, and 4 had partial gastrectomy; 28 had a low 2-hr. and 4 had a low 3-hr. excretion. The pattern of excretion in 5 normal subjects after doses varying from 0.5-25.0 g showed a departure from linearity for doses greater than 5 g. After a 5-g dose in 52 normal subjects the results for the 5-hr. excretion of xylose were identical with the results reported in the literature, the mean value being 35%, with a range of 23-48. Cumulative excretion of xylose over a 24-hr. period after a 5-g dose in 29 tests on 19 normal persons and 10 tests on 4 patients with gluten-induced enteropathy showed that the 5-hr. excretion was similar in both groups, but the patients with enteropathy excreted less in the first 2 hr. Study in more detail showed that normal subjects put out more than 50% of their 5-hr. excretion in the first 2 hr., but gluten-patients put out less than a third of their 5-hr. excretion in the first 2 hr. The max. excretion of xylose in 4 patients with partial gastrectomy was in the first hr., which is consistent with the

id entry of xylose into the small intestine
these patients. Using this modification,
airment of xylose absorption was demonstrated
28 cases, even when the total 5-hr. xylose
orption was normal; in some cases there were
er abnormalities suggestive of malabsorption,
reby supporting the view that the low 2-hr.
retion of xylose is usually attributable to
er intestinal malabsorption rather than de-
ed stomach emptying. It is concluded that a
ll p.o. dose of D-xylose (5 g) gives good
dence of small intestinal malabsorption when
excretion is followed in the urine; much
ter localization of the intestinal defect can
gained by measurement of the 2-hr. and 5-hr.
nary excretion after this dose. A normal 5-hr.
retion may be accompanied by a lowered 2-hr.
retion, thus still indicating the presence of
er small intestinal disease.

16 TOPICS IN CLINICAL MEDICINE. INCIDENCE
AND IMPLICATIONS OF LACTASE DEFICIENCY
MILK INTOLERANCE IN WHITE AND NEGRO POPULA-
NS. (E.) Bayless, T. M. (Johns Hopkins U.
Med., Baltimore, Md.) and N. S. Rosensweig.
ns Hopkins Med. J. 121(1):54-64, 1967.

clinical manifestations of lactase deficiency
milk intolerance include abdominal bloating
cramps, and diarrhea. Methods of confirming
agnosis of lactose intolerance or lactase
ciency include observation of patients after
estion of large amounts of lactose or milk;
of the lactose tolerance test; and assay of
ase activity in the intestinal mucosa. Lactose
rance tests were given to 40 healthy males
54 yr. old); there were 19 milk-tolerant
ects with no history of symptoms with milk
stion and 18 of the 19 had a rise in blood
r over 25 mg%; in contrast, 21 who were milk-
lerant had lower peaks and 15 had blood sugar
s of less than 25 mg%. None of the milk-
rant subjects had symptoms with a lactose
. Assay of jejunal mucosal biopsy specimens
lactase showed that 15 of the 21 milk-intolerant
ects had enzyme levels that were lower than
of the milk tolerant subjects; there were 6
ects who were milk intolerant but without
ase deficiency; 2 were lactose intolerant.
ncidence survey was performed on the same 40
thy male volunteers who were unselected
pt that there were 20 Negroes and 20 Caucasians;
bject had a peptic ulcer. These were inter-
ed for a history of milk intolerance; sugar
rance tests and jejunal biopsies for dis-
aridase assay were performed on all of them.
teen of 20 Negroes gave a history of milk
lerance in contrast to only 2 of 20 Caucasians;
f 20 Negroes had symptoms with the lactose
rance test and 15 had a flat lactose tolerance
e (less than 25 mg% rise); this was in con-
t to the Caucasian subjects, of whom only 2
similarly affected. Fourteen of 20 Negroes
) had lower lactase levels than any of the
-tolerant subjects; only 1 of the 20 Caucasian
ects had low lactase levels. The marked
racial difference suggests a genetic etiology for this lactase deficiency.

11517 A STUDY OF PROXIMAL AND DISTAL INTESTINAL STRUCTURE AND ABSORPTIVE FUNCTION IN IDIOPATHIC STEATORRHOEA. (E.) Stewart, J. S. (West Middlesex Hosp., England), D. J. Pollock, A. V. Hoffbrand, D. L. Mollin and C. C. Booth. Quart. J. Med. 36(143):425-444, 1967.

Jejunal and ileal biopsies, proximal absorption tests of the jejunum (xylose, glucose, folic acid, pyridoxine and ascorbic acid studies) and distal absorption tests of the ileum (vitamin B_{12} study) were carried out in 50 control subjects and 60 patients (aged 14-75 yr., 26 males and 34 females) with proven idiopathic steatorrhea. Control subjects revealed jejunal biopsy patterns predominantly of finger-shaped, narrow leafy and/or broad-based leafy villi (1 patient only). These villus changes occurred in a continuous sequence throughout the jejunal sections examined. Ileal biopsies obtained from 10 control subjects revealed finger-shaped villi in 5 subjects, a mixture of finger-shaped and narrow leafy villi in 4 subjects and narrow leafy villi in 1 subject. The jejunal patterns in biopsies obtained from the patient group revealed either flat mucosae or mucosae in a mosaic pattern, both showing a continuous progression of abnormal changes throughout the sections examined. These different mucosal alterations were found simultaneously at different levels in the same patient and in siblings. A convoluted pattern developed in those patients exhibiting flat mucosa and who were then fed a gluten-free diet. Ileal sections revealed either normal structure or less-involved structure as compared to jejunal sections. There appeared to be no relationship between the jejunal mucosal structure and absorptive capacity. Correlation did exist between both the ileal surface height and the vitamin B_{12} absorption as well as between the degree of steatorrhea and the degree of vitamin B_{12} malabsorption. It is indicated that the severity of steatorrhea is best assessed by the reserve absorptive capacity of the ileum rather than that of the jejunum.

11518 MALABSORPTION IN THE TROPICS: A SECOND LOOK. I. THE ROLE OF PROTEIN MALNUTRITION. (E.) Mayoral, L. G. (U. del Valle, Sch. Med., Cali, Colombia), K. Tripathy, F. T. Garcia, S. Klahr, O. Bolaños and J. Ghitis. Amer. J. Clin. Nutr. 20(8):866-883, 1967.

Adult patients (15) of a low socioeconomic level were divided into 2 groups: Group 1 (7 patients) presented with severe protein deficiency with 4 of these patients having severe hookworm infestation and Fe-deficiency anemia and Group 2 (8 patients) presented with both hookworm infection and anemia but no protein malnutrition. Those patients from Group 1 without hookworm infestation or anemia showed both abnormal small intestinal absorption and mucosal changes consonant with a malabsorption syndrome. Patients from Group 1 with all 3 conditions showed similar findings. Both patient groups showed regression of their malabsorption syndromes when placed on an adequate protein diet. None of the patients from Group 2 demonstrated any signs of malabsorption at any time. This suggests a noncausal relationship between horkworm disease and the malabsorption syndrome. In addition, the causal role of Fe-deficiency anemia in protein malabsorption is doubtful. It is noted, however, that in severe cases of Fe-deficiency anemia, secondary protein malnutrition may result from interference with the appetite process. In addition, the hookworm disease and Fe-deficiency anemia in patients suffering a concomitant malabsorption syndrome induced by protein malnutrition do not of themselves affect the potential regression of the malabsorption syndrome with proper protein regimen.

11519 INTESTINAL ABSORPTION AFTER GASTRECTOMY AND AFTER VAGOTOMY WITH DRAINAGE OPERATION. (Pol.) Cichecka, K. (2nd Intern. Dis. Clin., Cracow, Poland), M. Dabrowski, H. Driżdż, A. Jędrychowski, S. Kirchmayer and M. Mysik. Pol. Arch. Med. Wewnet. 38(6):693-701, 1967.

Intestinal absorption of fats, vitamin A, D-xylose and glucose was studied in 14 patients with partial gastrectomy (Group 1), in 12 with vagotomy with pyloroplasty (Group 2), and in 5 with vagotomy with antrectomy (Group 3). Fat-loading tests indicated an increased excretion of fats in all 3 groups. Impairment of fat absorption was most frequently found in Group 3 (4 of 5 patients), less frequently in Group 1 (6 of 14) and Group 2 (5 of 12). However, the degree of impairment was greatest in Group 1 (21.54 g in 24-hr. stools), lower in Group 3 (12.52 g) and lowest in Group 2 (7.26 g). Stools after gastrectomy contained mostly fatty acids, in Group 2 there was an increase of neutral fats and in Group 3 an approx. equal increase of fatty acids and neutral fats. The majority of patients with impaired fat absorption had no diarrhea, some even suffered from constipation. Diarrhea of short duration followed by periods of constipation was observed in 23% of the patients in all 3 groups. There was no correlation between loss in body wt. and the severity of impairment in fat absorption, probably because daily losses of fat in the stools were not large enough (15.9%) to produce diarrhea or a decrease in body wt. The serum carotene level was insignificantly lower in 2 of Group 2, 3 of Group 3 and 3 Group 1 patients. Decreased levels of serum vitamin A was found in 3 of Group 3, 4 of Group 1 and 1 of Group 2. After p.o. loading of vitamin A (150,000 U) the increase of serum vitamin A level was 35% smaller than normal after partial gastrectomy but in Group 2 and 3 it differed only slightly from normal. About 50% of the patients in all 3 groups showed impaired D-xylose absorption. An increase in glucose absorption was observed in the majority of patients with an av. of 31.2 g for patients wi vagotomy and 32.7 g for gastrectomy patients (av. norm 27 g).

11520 CARBOHYDRATE ABSORPTION IN MALNOURISHE CHILDREN. (E.) Bowie, M. D. (U. Cape Town, South Africa), G. O. Barbezat and J. D. L. Hansen. Amer. J. Clin. Nutr. 20(2):89-97, 1967.

Twenty children with severe protein-calorie malnutrition (kwashiorkor) were studied for carbohydrate absorption. Lactose malabsorption occurred in 65% of the children, and it was not transient. Return of lactose absorption to normal was not demonstrated even after 1 yr. of follow-up, but follow-up studies were limited i time and numbers. The malabsorption of lactose was due to diminished or absent lactase activit and this was presumably an acquired deficit secondary to the mucosal damage which occurs in malnutrition. No evidence was found of malabsorption of other disaccharides (sucrose and maltose), although diminished sucrase activitie were found in some patients. The evidence of lactose malabsorption from stool wt., lactic acid content and presence of sugar correlated well with the evidence of malabsorption obtaine by consideration of lactose tolerance tests and absorption ratios.

11521 ABSORPTION OF ^{131}I-TRIOLEIN IN POSTOPERATIVE GASTROINTESTINAL PARALYSIS. (E.) Póka, L. (Univ. Med. Sch., Pecs, Hungary) I. Földi, G. Czirbusz, M. Németh-Csóka, S. Fark and I. Bartek. Acta Chir. Acad. Sci. Hung. 8(2):183-189, 1967.

Gastrointestinal paralysis was experimentally induced in dogs, and the assimilation of ^{131}I-triolein, changes in the condition of gastrointestinal tract and in pancreatic activity wer studied. Postoperative findings were similar to those previously noted in humans, in that th absorption of triglycerides decreased significantly, the motor activity of the small intesti remained practically unchanged, the small intestine was only rarely distended, and the pancreatic enzymes were sufficient for hydrolyzing the foodstuffs admin. It is suggested that disturbances in absorption, rather than digestion, inhibit the utilization of triglycerides. During gastrointestinal paralysis the intraluminal conditions of the small intestine were found to be adequate for absorption and digestion. It is concluded that disorders of absorption must result from a reduction of the transport activity of the intestinal mucosa.

11522 GLUCOSE MALABSORPTION AND INTESTINAL HISTOPATHOLOGY IN Trichinella spirali INFECTED GUINEA PIGS. (E.) Castro, G. A.

. Massachusetts, Amherst), L. J. Olson and
D. Baker. *J. Parasit.* 53(3):595-612, 1967.

vitro and *in vivo* studies using guinea pigs
perimentally infected with *Trichinella spiralis*
nducted over a 28-day infection period showed
at the capacity of the small intestine to
sorb glucose was significantly reduced in
imals infected with 10,000 but not 5,000 larvae.
paired absorption was first detected in the
rst 75% of the intestine on day 3, then on day
for the last 25%. The first and second
arters were capable of normal glucose uptake
day 14, whereas uptake in the third quarter
mained impaired. On days 21 and 28 malabsorp-
on was observed only in the fourth quarter.
e impaired glucose uptake was associated with
e following histologic changes: a loss of nor-
l villous pattern, aberrant epithelial cells
d inflammation of the lamina propria.
ronologically, these alterations occurred in
e anterior half of the intestine during early
fection and later extended into the posterior
rtion. Likewise, there was a shift in the
lative distribution of worms from the anterior
the posterior end of the small intestine as
fection time progressed. Only a small fraction
a dose of 10,000 larvae could be recovered
om the small intestine following infection:
0% the first wk., 1.8% on day 14, 0.2% on day
and rarely any on day 28.

23 THE INFLUENCE OF CYTOSTATIC CHEMO-
THERAPY WITH AMETHOPTERIN UPON THE
PLY OF THIAMINE. (Ger.) Berndt, H. (Cancer
. Inst., Berlin) and I. Kutschke. *Klin. Wschr.*
16):845-847, 1967.

nary thiamine levels were studied in 27
ients with bronchiolar carcinoma treated with
g/day of methotrexate for 14 days. Three
ies of tests were made, the first with sub-
ts receiving chemotherapy only, the second
h 50 mg/day of thiamine, and the third with
mg/day of thiamine tetrahydrofurfuryldisulfide,
inning on the tenth day of chemotherapy.
nsketolase activity in RBC hydrolyzates was
o measured. Methotrexate induced malabsorp-
n of thiamine and the resulting thiamine
iciency was marked by a depressed urinary
retion of thiamine in the first series (from
to 136 µg/day; 0 and 20 days) and by de-
ased activity of transketolase in RBC (from
4 to 16.9 U). Intake of additional thiamine
not fully correct this situation; the corre-
nding values in the second series were from
to 145 µg/day and from 19.6 to 17.2 U. How-
r, in the third series the values were 150 to
270 µg/day and 18.9 to 22.9 transketolase U.
amine tetrahydrofurfuryldisulfide is absorbed
rapidly restores normal activity of the
nsketolase. To prevent thiamine hypovitaminosis,
s thiamine compound should be admin. during
cer chemotherapy.

11524 CRITICAL ANALYSIS OF AN ENTERIC ABSORPTION TEST. BEHAVIOUR OF HOURLY EXCRETION AND OF FLUID BALANCE IN THE COELIAC MALABSORPTION SYNDROME. (E.) Campos, J. V. M. (U. Sao Paulo, Brazil), D. Barbieri, G. Quarentei, J. M. M. Coronel and K. Hashisume. *Arq. Gastroent. (Sao Paulo)* 4(1):17-38, 1967.

An enteric absorption test was performed on 12 normal children (Group 1; 4-10 yr. old) and 11 (Group 2; 2-9 yr. old) with the celiac malabsorption syndrome; the clinical picture of the latter group was used due to its uniformity as an experimental model syndrome. Children with celiac malabsorption syndrome were divided into 2 groups: A, 8 with enteric histopathology characteristic for "gluten-induced celiac transformation" and B, 3 with histopathology characteristic of "catarrhal enteropathy" (varied degrees of thickening and shortening of villosities, with an intense lymphoplasmocytic infiltration of the villous membrane). Using 2 test substances simultaneously, D-xylose (5 g) and glycine (0.5 g/kg), and by standardizing hydration conditions, the following parameters were analyzed: 1) control of liquid balance; 2) study of the hourly partition of the urinary vol.; and 3) determination of the corresponding rates of eliminated test substances. Water intake (ml, av./m^2) for Groups 1 and 2 A and B were, resp., 323.0, 354.0 and 328.0, while urinary excretion (total, ml/m^2) were, resp., 606.4, 527.0 and 789.0. An obvious diuresis was noted. Urinary elimination of D-xylose (over a 5-hr. period) showed in Group 1 an av. of 30% of the ingested dose; in Group 2 A, this was 17.3% (below normal) and in Group 2 B, it was 24.0%. In Group 2 A, there was an delayed elimination of xylose and decreased values during the initial 2 hr.; Group 2 B more closely followed that of Group 1. Urinary elimination of glycine (over a 5-hr. period) showed, as a percentage of the admin. dose, 4.3%, 5.4% and 3.0%, resp., for Groups 1, 2 A and 2 B. In Group 1, there was significant elimination during the first hr., max. during the second hr., followed by progressive reduction and intense reduction during the final hr.; in Group 2 A, there was delayed elimination during the first hr., followed by significant increase in elimination during the third and fourth hr., and reduction during the fifth hr. In Group 2 B, glycine urinary elimination was characterized by nearly normal behavior. Fluid balance studies showed an osmotic diuresis, especially caused by D-xylose. It was shown that osmotic phenomena are not limited only to depuration, but also exist in the small intestine, especially in Group 2 A, where they were associated with the process of stagnation of the hypotonic loops. Absorption of the test substances was dependent not only on the functional conditions of the enteric epithelium, but also could be related to abnormal stagnation, osmotic dilutions and movement of intestinal fluids. D-Xylose, being more intensely depurated of the 2 test substances, more exactly reflected the phenomenon of intestinal absorption. When analyzing results of an enteric absorption test as used in this study, an upward deviation from normal may attest to the great capacity of absorption of the mucous surface of the normal small intestine.

absorption of the mucous surface of the normal small intestine.

40 COLITIS CYSTICA PROFUNDA. (E.)
Wayte, D. M. (Armed Forces Inst. Path.,
hington, D. C.) and E. B. Helwig. Amer. J.
n. Path. 48(2):159-169, 1967.

otal of 24 patients (15 men, 9 women) with
mucosal mucous cysts of the rectum and colon
described. These were divided into 2 groups:
up 1, 5 men (4-68 yr. old, mean age of 36
) with diffuse type of profound cystic colitis,
which cysts were located in extensive areas
the large intestine; and Group 2, 19 subjects
men, 20-51 yr. old, with a mean age of 28 yr.,
9 women, 20-52 yr. old, with a mean age of
with the localized type of profound cystic
itis, in which the cysts were confined to a
tinct area of the rectum at a distance
ween 5-12 cm from the anal margin. Presenting
ptoms of the 5 subjects with the diffuse
e of colitis included clinical ulcerative
itis of 4 and 3 yr. duration in 2 patients;
onic infective dysentery caused by Salmonella
port that was resistant to antibiotic therapy
1 (the yound child); and 2 with intermittent
tal bleeding. In the 19 with localized
itis, presenting symptoms included bright
rectal bleeding, mucous discharge, intermittent
rrhea and rectal prolapse. The most frequent
nical sign in the latter group was a mass,
yp or plaquelike-thickening in the rectum at
istance between 5-12 cm from the anal margin;
f these had a history of previous surgery in
affected area of the rectum. Of those with
diffuse form, the 2 with ulcerative colitis
e a good recovery, and 2 with multiple polyps
overed after colectomy and local resection.
19 with the localized type, follow-up was
cessful in 17; 12 suffered no further
ptoms after local resection, and 4 continued
have colitis symptoms. Only 1 woman required
ther local rectal surgery and removal of
mucosal cysts for continuing symptoms 11 yr.
er the first operation, and made a good
overy. It is thought that the submucosal
ts and glands found in this condition result
m the extension of surface mucosa along
nulation tissue tracts created through the
cularis mucosa. The differentiation from
nocarcinoma, and particularly the importance
careful cytologic evaluation, is stressed,
order to avoid a mistaken diagnosis of malig-
cy (which was done in one case in this series).

1 CANCER OF THE COLON: THE INFLUENCE OF
THE NO-TOUCH ISOLATION TECHNIC ON
VIVAL RATES. (E.) Turnbull, R. B., Jr.
eveland Clin. Found., Ohio), K. Kyle, F. R.
son and J. Spratt. Ann. Surg. 166(3):420-427,
7.

rative manipulation of a cancer-bearing segment
colon will increase the incidence of fatal
astasis. A computer analysis study was undertaken of the results of 2 methods of surgical treatment of 896 patients with cancer of the colon; 664 patients were treated by 1 surgeon, who used a no-touch isolation technic when resection was indicated, and 5 other surgeons treated 232 patients, using a conventional technic when resection was indicated. With the no-touch isolation technic, the cancer-bearing segment was not manipulated or handled in any manner until after the lymphovascular pedicles were divided and ligated and the colon was divided at the elected sites for resection; the conventional technic was characterized by ligation and division of the lymphovascular pedicles after mobilization of the cancer-bearing segment. The death rate from metastatic cancer was much greater during the 2 yr. after the conventional technic resection; most of the deaths were due to metastasis to the liver, and it is suggested that this greater incidence of fatal hepatic metastasis was secondary to operative manipulation of the cancer-bearing segment. The age-corrected 5-yr. survival rate in 460 patients who underwent "resection for cure" with the no-touch isolation technic was 81.6%. It is suggested that these greatly improved survival rates were due to use of the no-touch isolation resection method and that the heretofore conventional manipulative resection technics for cancer of the colon should be abandoned.

11542 CAECAL TUBERCULOSIS. (E.) Anscombe, A. R. (Roy. Infirm., Manchester, England), N. C. Keddie and P. F. Schofield. Gut 8(4):337-343, 1967.

Nine cases (2 men, 7 women; 25-88 yr. old) of tuberculosis of the cecum are described. Five of 9 patients gave a history of 6 mo. or less, and deterioration in general health was rapid, wt. loss and anemia being found in all patients. Abdominal pain was present in 8 of 9, diarrhea in 7, being constantly present in 4; 5 had blood in the feces. A mass in the right iliac fossa was found in 8 of 9 patients; in 7 (all female), a provisional clinical diagnosis of carcinoma of the cecum was made. Seven patients studied by a Ba enema showed an abnormal appearance of the right colon, being interpreted as due to carcinoma. One of 9 cases had tubercle bacilli in the sputum, and 1 of 2 patients had the same in feces. All patients were subjected to laparotomy, and a right hemicolectomy was done in 8; 7 of 8 survived the operation, and 6 remained well to the time of report, the period of follow-up being 1-12 yr. Two of the longterm survivors had antituberculous chemotherapy with no apparent advantage over the 4 patients who were not so treated. All cases in this series were hypertrophic; the cecum was the site of max. involvement, with secondary affection of the regional lymph nodes; the terminal ileum was involved only in advanced cases. It is suggested that, on the basis of clinical and pathological evidence presented, this condition should be designated "cecal tuberculosis" and that use of the term "hypertrophic ileocecal tuberculosis" should be discontinued. This series demonstrates that cecal tuberculosis must be kept in mind as a differential diagnosis of carcinoma.

11543 ENVIRONMENTAL FACTORS OF CANCER OF THE COLON AND RECTUM. (E.) Wynder, E. L. (Sloan-Kettering Inst. Cancer Res., New York, N. Y.) and T. Shigematsu. Cancer 20(9):1520-1561, 1967.

A retrospective study of 791 patients (458 men and 333 women, plus age-matched controls) with cancer of the large intestine is presented. Colonic cancer appeared to be more common among the Jewish population in New York City; this trend also was observed for men in this study, whereas among Jewish women there was an excess of cases of rectal as well as colonic cancer. The socioeconomic status of patients with colonic cancer appeared to be somewhat higher than that of patients with rectal cancer. Data from this investigation, when taken alone, could not establish a major environmental factor or factors relating to the development of cancer of the large intestine. On the basis of the total epidemiologic evidence with which the data of this study were consistent, dietary factors appeared to be associated with the etiology of cancer of the large intestine; the dietary pattern which may fit the distribution of cancer of the large intestine includes a high intake of fats; the effect of this pattern appeared to be more marked for cancer of the colon than cancer of the rectum. Dietary information on specific food items as obtained in retrospective histories was of little value in determining the influence of diet on colonic cancer. Epidemiologic evidence suggests some differences in the etiology of cancer of the colon and rectum; the epidemiology of cancer of the rectosigmoid regions appeared to fit more closely with cancer of the colon than with cancer of the rectum. There was a statistically significant association of obesity to cancer of the large intestine from the cecum to the sigmoid colon in men. Among women a number of patients with cancer of the sigmoid weighed somewhat less than controls, whereas patients with disease of other areas of the large intestine were somewhat heavier, although not significantly so, than control cases. These findings related to body wt. may represent a secondary rather than a primary association. There was a slight association between cigar smoking and cancer of the colon in men; cigar smoking was related to noncigarette smoking, particularly in men with cancer of the sigmoid colon. Both of these factors related to obesity and a Jewish affiliation; cigar smoking and noncigarette smoking are regarded as secondary and not primary associations. Constipa tion was associated to a minor degree with cancer of the large intestine. Among men it affected principally patients with cancer of the sigmoid and to a smaller extent the other sites; among women, the association held only for groups with cancer of the cecum through the descending colon. An association of obesity to constipation was found. Constipation findings therefore, may also represent an incidental rather than a primary association. No significan relationship was found between cancer of the large intestine and any medical disease apart from ulcerative colitis. There was no relationship to any kind of previous surgery. The relationship to appendectomy suggested by some investigators appeared to relate to differences in epidemiologic background that determines the chance of appendectomy rather than being etiologically related to a large intestinal cancer. Some genetic or familial basis seemed to exist for cancer of the large intestine, especially among younger individuals with large intestinal cancer. Patients with cancer of the large intestine appeared to be particularly prone to develop a secondary primary lesion within the large intestine, a finding of particular clinical interest. It is suggested that analytical chemical, biochemical and bacteriological studies be undertaken to determine differences in the composition of feces as may exist among populations with high and low rates of cancer of the large intestine.

11544 IDENTIFICATION OF THE ROUTE OF ACTION OF THE CARCINOGEN 3:2'-DIMETHYL-4-AMIN BIPHENYL IN THE INDUCTION OF INTESTINAL NEOPLASI (E.) Cleveland, J. C. (Hahnemann Med. Coll. Hosp., Philadelphia, Pa.), S. F. Litvak and J. W. Cole. Cancer Res. 27(4):708-714, 1967.

Wistar rats of both sexes were divided into 4 groups; Group 1 received weekly s.c. inj. of 20 mg of 3:2' dimethyl-4-aminobiphenyl; Group 2, approx. 50% of the colon was defunctionalized by taking out of continuity the midportion of the colon but allowing it to remain *in situ* with the nerve-blood supply intact; the proximal end was closed and the distal end exteriorized on the abdominal wall as a mucous fistula; intestinal continuity was restored by colocolostomy with end-to-end anastomosis; after recovery the rats received the drug as in Group 1; Group 3, subtotal colectomy was performed resecting the colon from a point just proximal to the ileocecal valve to within 1 cm of the anal orifice; continuity was restored by ileoproctostomy; the rats then received the drug as in the previous 2 groups; and Group 4, the controls, received inj. of peanut oil only. In Group 1, 7 of 17 (41%) developed intestinal tumors; 6 were in the colon or rectum and 1 in the ileum. In Group 2, 9 of 18 (50%) developed intestinal tumors; 6 were in the colon or rectum, 2 in the rminal ileum and 1 in the jejunum. All tumors ccurred in the intestine that had direct contact th the fecal stream, and none of the animals ad any lesion occurring in the viable, efunctionalized loop. None of 6 animals in roup 3 developed intestinal tumors, and none Group 4 developed intestinal neoplasia. nterpretation of these experiments suggests at the chemical is absorbed from the inj. site, odified, probably in the liver, excreted into e bile, and neoplasia induced by direct ntact of feces with intestinal mucosal cell.

545 INTRALUMINAL CHEMOTHERAPY (HN2 OR 5-FU) ADJUVANT TO OPERATION FOR CANCER OF IE COLON AND RECTUM. II. FOLLOW-UP REPORT OF CASES. (E.) Rousselot, L. M. (St. Vincent's sp., New York, N. Y.), D. R. Cole, C. E. Grossi, J. Conte and E. M. Gonzalez. Cancer (5):829-833, 1967.

5-yr. progress report is presented of a method intraluminal chemotherapy adjuvant to operation r cancer of the colon and rectum. This chnic involves sequestering the pathological gment between tape ligatures; a cancericidal ug is then inj. into the lumen within the ped area. Clamping of the pedicle vessels designedly-delayed 30 min. in order to allow x. dosage absorption. In the 5-fluorouracil-eated group, the agent is repeated i.v. on stoperative days 1 and 2. A total of 97 tients was followed up to 5 yr. in the eated series, and 268 patients were followed the control series. Nitrogen mustard and fluorouracil were used. There was no significant rise in morbidity or mortality associated th the technic. Survival follow-up studies of e nitrogen-mustard-treated group at the end 5 yr. showed no improvement over the controls. wever, in the 5-fluorouracil-treated group patients, the increased trend in survival noted 3 yr. continued to be sustained at 4 yr. t time of report).

546 EFFECT OF COLOSTOMY ON EXPERIMENTALLY PRODUCED NEOPLASMS OF THE COLON OF THE T. (E.) Navarrete, A. (Baylor Univ. Coll. d., Houston, Tex.) and H. J. Spjut. Cancer (9):1466-1472, 1967.

order to determine the effect of the fecal ream in the pathogenesis of experimentally-oduced colonic tumors in Wistar strain rats emale), simple colostomies were performed in e left colon of 57 rats at approx. 4 cm above e anus. A total of 54 rats received daily c. inj., 5 days/wk., of the carcinogen 2'-dimethyl-4-aminodiphenyl at a dosage of mg/day/100 g. Of the 54 rats, 17 (31.4%) veloped either hyperplasia, adenomatous polyps carcinoma of the large intestine proximal the site of colostomy. None of the 54 rats veloped any lesion distal to the colostomy. None of the 3 control rats with colostomies developed any kind of tumor. Of the colonic lesions that developed, 4 were carcinomas, 12 were adenomatous polyps and 12 were hyperplasias. All hyperplasias developed at the edge of the colostomy. It is concluded that diversion of the fecal stream prevents development of colonic neoplasms in Wistar rats in this experimental situation.

11547 RADIOGRAPHIC FEATURES OF THE MEGASIGMOID SYNDROME. (E.) Finby, N. (St. Luke's Hosp., New York, N. Y.) and E. Kraft. Johns Hopkins Med. J. 120(6):393-400, 1967.

The most common roentgenologic picture of megasigmoid consists of an extremely long and widened sigmoid whose loops are redundant. Frequently the sigmoid itself is observed beneath the diaphragm, therby simulating volvulus of the sigmoid. Chest radiographs may disclose an elevation of the left hemidiaphragm by the sigmoid or the positioning of the sigmoid between the diaphragm and the liver. The sigmoidal loops in this pattern are gas-filled and quite mobile in the abdominal cavity. The proximal colon is usually impacted with fecal material, which is passed infrequently into the sigmoid. Subsequent rectal impaction may occur and this is often hard to differentiate from that mechanical obstruction which results from a true sigmoid volvulus. A second common roentgenologic picture reveals the presence of large fecal masses in the sigmoid. These may remain for long periods of time leading eventually to mucosal ulceration. A third pattern is characterized by the sigmoid being filled with a continuous column of fecal material, rather than discrete fecal masses, which are sometimes surrounded by marginal gas pockets suggestive of intra-abdominal perforation. Such a spurious picture of perforation is especially evident when radiographs are taken with the patient in the erect position. Localization of this amorphous fecal mass in the sigmoid may eventually result in a terminal toxemia. These roentgenologic signs, when they are of long duration, should suggest a diagnosis of megasigmoid, especially in the older neuropsychiatric patient.

11548 IMMUNOGLOBULIN A: LOCALIZATION IN RECTAL MUCOSAL EPITHELIAL CELLS. (E.) Gelzayd, E. A. (U. Chicago Sch. Med., Ill.), S. C. Kraft and F. W. Fitch. Science 157(3791):930-931, 1967.

Immunofluorescence studies with monospecific antiserums to human serum immunoglobulins were performed on normal subjects and patients with various intestinal diseases (not specified); a direct immunofluorescent technic with goat antiserums (labeled with fluorescein isothiocyanate) to human serum immunoglobulins A, G and M, and sheep antiserum to rabbit γ-globulin was used. Indirect fluorescent antibody studies were done with rabbit antiserum to human immunoglobulin D. Immunospecific staining for immunoglobulin A was consistently revealed within the apical portion of the cytoplasm of mucosal epithelial cells of normal and abnormal human rectal biopsies; similar findings were noted in a smaller number of small intestinal, colonic and appendiceal tissues. The immunoglobulin A was not seen near the nuclei at the basal aspect of the cells or in the mucus-containing portion of the goblet cells; the cellular fluorescence was distributed along the entire epithelial layer lining the glandular duct, occasionally within the ducts and in the particulate matter of surface mucus. Immunoglobulins M, G and D were not demonstrated within mucosal epithelial cells. The predominance of lymphoid cells containing immunoglobulin A in the lamina propria of intestinal tissues was confirmed. The findings of immunoglobulin A within human intestinal epithelial cells may represent a transepithelial cell pathway for immunoglobulin A between the lamina propria and the luminal surface.

11549 ISO-ANTIBODIES TO COLON. (E.)
Ford, H. (U. Chicago, Ill.) and J. B. Kirsner. Int. Arch. Allerg. 31(5):449-454, 1967.

Young adult New Zealand white rabbits were inj. with normal homologous colon and Freund's complete adjuvant, and altered (inflamed) rabbit colon alone or with Freund's complete adjuvant. A course of immunization consisted of inj. 0.5 ml of a 1:10 emulsion of homogenized tissue in saline into each of 5 portals (i.m., i.p., s.c., i.v., and intradermal), 3 times a wk. for 3 wk. Each animal in both control and test groups received a total of 2.25 mg of tissue during each course of sensitization. In all but 6 animals the course of immunization was repeated up to 6 times (with a 2- or 3-wk. interval between courses), so that most animals received 13.5 g of tissue over a period of 9 mo. Sensitivity was tested using the hemagglutination test and agar gel-double diffusion test. Isologous circulating antibodies were induced only by inj. of large quantities of inflamed rabbit colon, together with Freund's complete adjuvant. Circulating antibodies were not demonstrable after inj. of normal homologous colon and Freund's complete adjuvant, nor after the inj. of inflamed rabbit colon alone.

11550 INCIDENCE OF DIVERTICULITIS. (E.)
Kyle, J. (Aberdeen Roy. Infirm., Scotland), A. O. Adesola, L. F. Tinckler and J. De Beaux. Scand. J. Gastroent. 2(1):77-80, 1967.

The hospital admission rates for symptomatic colonic diverticulitis in the populations served by the main teaching hospitals in Fiji Singapore, Nigeria and North East Scotland were estimated. The condition was found to be very rare in nonEuropeans, occurring in approx. only 1 person/million/yr. There was very little diverticulitis among the Malays, Chinese and Indians in Singapore. The incidence among non-Europeans in Fiji was probably slightly higher, but the numbers were too small for valid comparisons. Admission rates for diverticulitis was some 40-fold greater among Europeans living in the Tropics, and about 80-fold greater in Scotland. Among the Scottish cases, the disease appeared to be slightly more common in men under 50 yr., while from 70 yr. old and onwards, females predominated. Among the 206 Scottish patients, the av. age was 68 yr., while for Europeans in Singapore it was 59 yr. and in Fiji, 60 yr. In contrast, the Chinese patients in Singapore and the Nigerians both had av. ages of 54 yr., and Fijians av. 32 yr. It is concluded that the differences delineated in this study are due principally to the greater age and low-residue diet of the European populations.

11551 APPENDICECTOMY IN MEN. (E.)
Barraclough, B. M. (Graylingwell Hosp., Sussex, England). J. Phychosom. Res. 11(2):203-206, 1967.

A psychiatric study is presented of men (61) who had an appendectomy for pain in the right lower abdomen. All patients were interviewed after recovery from the operation and while in the hospital, and all completed the Tayler Manifest Anxiety Scale. Histologically, there were 48 abnormal and 13 normal appendices. The mean age of those with an abnormal appendix (30.8 yr.) was greater than those with a normal appendix (25.1 yr.). The normal group obtained much higher manifest anxiety scale scores (mean of 21.23 against 13.56 for those with an abnormal appendix). Four abnormal and 9 normal appendix patients required referral to a psychiatrist. The normal group had more frequently suffered parental loss before 16 yr. of age. This study has shown that among a group of patients who have pain in the right iliac fossa without any organic cause, indices of psychological disturbance are far more common than in a comparable group of patients who had appendicitis. The likely explanation for the abdominal pain is that it was one among a number of symptoms, all psychological in origin but accepted by the patient and doctor as the point of therapeutic attack.

11552 THE ORIGIN OF INFLAMMATION MACROPHAGES FROM BLOOD MONOCYTES OBSERVED IN ACUTE APPENDICITIS. (Ger.) Leder, L. D. (U. Kiel, Germany) and C. Pörksen. Klin. Wschr. 45(14):721-726, 1967.

esh human appendices were split longitudinally,
lf of each were fixed in formalin and prepared
r histology; the other half was cut into
ozen sections, tested for unspecific esterases,
l the cells in the transected blood vessels
served. The nucleated cells were differentially
unted in groups of 1000 under oil immersion;
served were granulocytes with segmented
clei, esterase-positive blood monocytes and
terase-negative lymphocytes. Eleven of the
pendices showed no changes from the normal
ndition and these served as controls; 33
owed all the signs of acute inflammation;
e connective tissue and the muscularis were
filtrated by numerous inflammatory cells
l large numbers of lymphocytes had accumulated
the blood vessels. A significant increase
the number of intravascular blood monocytes
s found. Migration pictures of monocytes
l striking morphologic and histochemical
milarities and even relationships between
ood monocytes and many inflammatory
crophages could be observed. These findings
dicate that inflammatory exudate macrophages
velop almost exclusively from migrated blood
nocytes. No evidence for the origin of
crophages from the local cells or lymphocytes
uld be found. The peritoneal macrophages also
em to represent migrated and transformed
ood monocytes.

553 TREATMENT OF CHRONIC RECTOSIGMOIDITIS.

0 ULCERATIVE OESOPHAGITIS IN ASSOCIATION
WITH ULCERATIVE COLITIS. (E.)
ndorff, C. (St. Thomas's Med. Sch., London)
N. W. T. Grieve. Gut 8(4):344-347, 1967.

-yr.-old white male presented with a 7-yr.
ory of intermittent joint pain and fever, 6
of episodes of diarrhea (more recently with
d and mucus in stools) and dysphagia of
easing severity for 2 yr.; on separate
sions he had been diagnosed and treated for
e rheumatic fever, diarrhea and buccal
ration, and finally ulcerative colitis. For
. he had been on continuous steroid therapy.
ure of an oropharyngeal swab revealed a mixed
th of commensals and included a scanty growth
Lancefield group A β-hemolytic streptococcus.
oidoscopy to 15 cm revealed a grossly ab-
al rectal and sigmoid mucosa with a finely
ular, hemorrhagic pattern, with several large
rs with hemorrhagic bases. Ba enema revealed
iderable ulceration and pseudopolyp formation
just above the cecum to the descending colon;
wallow revealed gross irregularity and ulcera-
in the lower two-thirds of the esophaus,
esting that the esophagitis might be monilial.
hagoscopy showed shallow ulceration of the
hagus, with gross diffuse irregularity and
p formation. Bacteriological examination of
hageal fluid aspirate showed Gram-positive
i in pairs and clumps, with pus cells, but
ure, including a culture on Sabouraud's
um, grew commensals only, and no Candida
cans. The patient was treated with Nystatin
nges 500,000 U 4 times/day, with rapid
ovement of dysphagia; prednisone was gradually
aced by prednisolone disodium phosphate 20
etention enemas once/day, with considerable
ovement in diarrhea. Sigmoidoscopic examina-
1 yr. after discharge revealed a uniformly
ular and hemorrhagic mucosa, compatible with
ulcerative colitis; esophagoscopy showed
iple polyps and papilliferous lesions
ughout the esophagus, with the mucous mem-
e covering these lesions, and between them,
rently normal. This report represents the
t in the British literature of multiple
rations of the esophagus in association with
rative colitis, and describes a possible new
lication of protcocolitis.

1 TREATMENT OF ULCERATIVE COLITIS BY
RESTRICTION OF CARBOHYDRATES. (Ger.)
, W. (St. Julien Strasse 29/1, Salzburg,
ria). Wien. Med. Wschr. 117(25-26):660-662,
.

ents with ulcerative colitis (14 men, 26
n) were treated for an av. period of 13 mo.
on a carbohydrate-poor diet; diagnosis of
disease was made by clinical findings,
oscopy, biopsy and radiology. The patients
ived a diet restricted to 60 g of carbo-
ate/day excluding cereals and cereal products; fat and protein intake was increased to make up the caloric deficit. Of 40 patients, 35 showed definite improvement while 5 were not helped; these 5 underwent antibiotic, sulfonamide and glucocorticoid therapy, and autoimmune studies, as well as carbohydrate restriction. The 35 subjects aided by diet therapy presented definite objective evidence of improvement although some residual damage remained (pain in the abdominal region); bleeding ceased, the color of the mucosa as seen by rectoscopy became normal, blood Fe conc. increased, wt. increased and mood and outlook improved.

11642 FOOD SENSITIZATION IN PATIENTS WITH ULCERATIVE COLITIS AND SPASTIC COLITIS. (Pol.) Romański, B. (1st Intern. Dis. Clin., Danzig, Poland), Z. Jancelewicz and A. Świderska. Pol. Tyg. Lek. 22(22):823-826, 1967.

Antibody determinations against milk, flour and egg white using the passive agglutination method were performed on the sera of 40 patients; 11 with ulcerative and 29 with spastic colitis. High antibody titers against milk were obtained in 65%, against wheat flour in 46% and against egg white in 54%. In 33 patients intestinal symptoms were aggravated by ingestion of these foods and in 19 cases a correlation between high antibody titers and aggravation of symptoms could be demonstrated. Antibody levels did not correlate with the clinical picture and duration of the disease. These high titers in sera of patients with colitis indicate an allergic process but cannot be used for evaluation of disease severity or for prognosis. It was noteworthy that 29 (72.5%) of the patients studied had symptoms of allergies: eczema and urticaria in 17, bronchial and nasal catarrh in 11 and bronchial asthma in 1 patient. It is concluded that sensitization to foods is 1 of the important factors in the etiology and pathogenesis of ulcerative and spastic colitis.

11643 ANTIBIOTIC TREATMENT IN ULCERATIVE COLITIS. EFFECTS ON SMOOTH MUSCLES. (Pol.) Gibiński, K. (3rd Intern. Dis. Clin., Katowice, Poland) and Z. Herman. Pol. Arch. Med. Wewnet. 38(5):583-589, 1967.

Cecal and gastric ulcers were induced in white male Wistar rats of 200-300 g wt. Phenylbutazone in 100 mg/kg amounts was inj. i.p. daily for 6 days in 23 rats while 23 control rats received 0.1 ml/100 g body wt. of 0.9% NaCl soln. The animals were sacrificed after 6 days. All phenylbutazone-treated animals showed ulceration of the cecum and gastric mucosa. The cecum in all animals was suspended in Tyrode's soln. and tension, amplitude, and frequency of contractions were recorded on a kymograph before and after addition of the antibiotics. The contractions of the normal cecum were stimulated by 0.1 mg/ml of chloramphenicol (Chloromycetin) in the Tyrode's soln., were inhibited by 0.25 mg/ml and completely paralyzed by 0.5 mg/ml. Chloramphenicol stimulated ulcerated cecum in 0.1-0.5 mg/ml amount but completely paralyzed it in an amount of 1 mg/ml. Pyrrolidinomethyltetracycline in 0.1-0.25 mg/ml amount did not change peristalsis of the normal cecum, but 0.5 mg/ml caused paralysis. With the ulcerated cecum this drug enhanced peristalsis in 0.1-1 mg/ml amounts but paralyzed them when 2 mg/ml were used. Tetracycline affected the normal cecum in the same way, 0.1 mg/ml inhibited it, and larger amounts paralyzed the ulcerated cecum. Erythromycin had the weakest direct effect on the cecum; in 0.1-2.0 mg/ml conc. it had no effect on normal and ulcerated cecum but at 4.0 mg/ml completely inhibited peristalsis. Routine admin. of antibiotics in ulcerative colitis should be discouraged except in cases of severe complications.

11644 A REVIEW OF THE USE OF TANNIC ACID IN PATIENTS WITH ULCERATIVE COLITIS. (E.)

Janower, M. L. (Massachusetts Gen. Hosp., Boston), L. L. Robbins and D. E. Wenlund. Radiology 89(1):42-43, 1967.

The clinical records of 507 patients who were diagnosed as having ulcerative colitis at the Massachusetts General Hospital during the period of 1944-1960 were reviewed, in retrospect, with the aim of determining the incidence of liver disease as related to Ba enema admin. Of the 104 patients who had had no Ba enema studies, 17 patients had a total of 26 liver function tests with all but one being considered normal. Seven patients with jaundice form an obvious cause (6 from postoperative sepsis and 1 with alcoholic cirrhosis) were omitted. Of the 403 patients with at least 1 Ba enema study, 127 had a total of 223 liver function tests. Of these, 61 patients who had 96 tests before enema had 5 tests which were considered abnormal, while 26 patients with 52 tests within 1 mo. after enema had 8 abnormal tests and 40 patients with 75 tests had 10 abnormal values. Review of the clinical records of these patients with abnormal tests did not show any correlation with admin. of Ba. Those patients whose Ba enemas preceded their jaundice were found to be suffering from metastatic carcinoma (1), infectious hepatitis (2), syndrome of ulcerative colitis, arthritis and hepatitis (2) and postoperative sepsis (10).

11645 THE ROLE OF ALLERGIC AND PSYCHIC FACTORS IN THE PATHOGENESIS OF ULCERATIVE AND SPASTIC COLITIS. (Pol.)

Romański, B. (1st Intern. Dis. Clin, Danzig, Poland), Z. Falicki, and Z. Jancelewicz. Pol. Arch. Med. Wewnet. 38(4):487-493, 1967.

Forty patients (20 males and 20 females) aged 20-67 yr. with large intestinal disturbances of 1-10 yr. duration were subjected to intensive physical, psychiatric and allergologic examinations. The probable precipitating factors among the 11 cases of ulcerative colitis studied were: psychic trauma, 5 cases; inflammation of the ovaries, 1 case; vitamin B_{12} inj., in 1 case. Among the 29 cases of spastic colitis: psychic trauma, 5 cases; severe infectious diseases, 5 cases; dietary indiscretion, 5 cases. In 22 patients infection within the abdominal cavity preceded the onset of the disease. Allergic conditions (determined clinically and immunologically) could be demonstrated in 38 of the 40 patients. Seventeen patients had hives or other skin conditions, 11 sinus or respiratory symptom and 1 had asthma. Positive skin tests could be demonstrated in 25 patients. In many there was a correlation between aggravation of symptoms by certain foods and a high level of reagins to these foods in their blood. Psychic disturbance were noted in 38 cases (14 had hysterical syndromes, 9 neurasthenia, 10 mixed syndromes and 5 other symptoms). In 22 patients the psychiatric syndromes existed before the onset of colitis, in 13 they accompanied the somatic symptoms, and in 3 cases appeared after the onse of the disease. Sexual disturbances were noted in 15 patients. It is concluded that infectious allergic, psychic and sexual factors play a role in the pathogenesis of colitis. A possible mechanism of action of these factors in causing the disease is briefly discussed. It is recomme that treatment should be based on cooperation between internist and psychiatrist.

11646 EARLY SURGERY IN THE MANAGEMENT OF SEVERE ULCERATIVE COLITIS. (E.)

Goligher, J. C. (Gen. Infirm., Leeds, England), F. T. De Dombal, N. G. Graham and G. Watkinson. Brit. Med. J. 3(5559):193-195, 1967.

Of the 74 patients who were treated for severe attacks of ulcerative colitis, 43 were treated by early surgery after failure to respond to intense, conservative therapy. The patient age distribution relative to the time of severe attack was 12 (0-19 yr.), 35 (20-39 yr.), 25 (40-59 yr.) and 9 (60 yr. and over). The types of surgery employed were proctocolectomy and ileostomy (40 patients), colectomy and ileostomy (1 patient), rectal excision and ileostomy (1 patient), and laparotomy and subsequent closure (1 patient). Initial medical therapy usually included large systemic doses of corticosteroids often combined with salazosulfapyridine. ACTH inj. (max. of 100 U/day) were also given to some patients. There was also a need for replacement therapy at times. Indications for early surgery included persistent massive hemorrhage or signs of perforation; sudden deterioration in the general health of a patient; no response to conservative therapy in patients over 60 yr. of age, and failure of significant improvement in younger patients after 4-5 days of intense medical therapy. There was only 1 death which occurred

29-yr.-old man who succumbed postoperatively
he effects of liver cirrhosis; this yielded
t mortality rate of 1.3% for all patients
ied, a significantly lower-rate than that for
previous decade (11.3% during the 1952-63
od). Of the 4 patients over 60 yr. of age
were operated upon, none died as a result of
ery as compared to the 50% death rate during
1952-1963 period.

7 A SOCIO-ECONOMIC STUDY OF PATIENTS WITH
ULCERATIVE COLITIS. (E.) Bonnevie, O.
tofte Hosp., Copenhagen). Scand. J. Gastroent.
:129-136, 1967.

naterial comprised 222 patients with ulcera-
colitis, who on admission to the hospital
ng the 5-yr. period 1960-1965 were permanent
dents in the county district of Copenhagen or
nunicipality of Gentofte, Denmark, the
ation of which was used as control material.
naterial was subdivided into 21 socio-economic
s. Among the patient population, 61.1% of
cases of ulcerative colitis occurred in men
20-50 yr., and 83.3% in women aged 20-60
the ratio of women to men was 1.5:1. In
control material, where this ratio was 1:1,
were children under the age of 14, against
among the patients. It was shown with
stical significance that within the 2
-economic subgroups "civil-servants +
ied grades", and "wage-earners", the patients
found at a relatively higher educational
conomic level. The distribution among the
socio-economic groups was the same as in
control material.

ULCERATIVE COLITIS IN CHILDREN.
REASSESSMENT OF A DILEMMA. (E.)
mott, J. F., Jr. (U. Michigan Med. Sch.,
rbor) and S. M. Finch. J. Amer. Acad. Child.
iat. 6(3):512-525, 1967.

ficant emotional illness was found to be
iated with the occurrence of ulcerative
is in a series of 49 children (26 boys. 23
; 2-16 yr. old) studied over a 10-yr. period.
e 26 boys, 11 had predominantly personality
ders, either passive-aggressive or passive-
dent, 8 had predominantly compulsive
nality types and 6 were of a mixed type. Of
3 girls, 11 had relatively typical compulsive
nalities, 2 had a passive-aggressive
nality disorder, and 9 had a relatively
mixture of compulsivity and such infantile
s as dependence and passive-aggressive
ior. Diagnosis was deferred in 2, a boy
girl, who were 2 and 3 yr. old, resp. Of
o received the most intensive psychiatric
ement (inpatient care), there were 16 boys
girls, ranging from 6-15 yr. old; the
n of hospitalization varied from 5-36 mo.,
an av. of 14 mo. Psychological improvement
oted in all but 4 patients treated
sively, 2 of whom died; 18 of 24 (75%)
treated intensively required subtotal colectomy with ileostomy as part of their total management. Although significant improvement in the emotional states was noted in the majority of the patients treated, this improvement was not associated with reversal or parallel improvement in the intestinal disease, confirming impressions that other etiological factors play a role in maintaining the progression of the disease. A pilot study in which serial samples of 2 of the patients' lymphocytes were mixed with normal colon cells demonstrated a persistent state of altered immunity over a period of 6 mo., in spite of changes in the emotional functioning and in the clinical expression of the disease.

11649 PSYCHIATRIC STUDY OF A CONSECUTIVE SERIES OF 34 PATIENTS WITH ULCERATIVE COLITIS. (E.) Feldman, F. (Cedars-Sinai Med. Ctr., Los Angeles, Calif.), D. Cantor, S. Soll and W. Bachrach. Brit. Med. J. 3(5556):14-17, 1967.

Each of 34 patients (17 male, 17 female) with ulcerative colitis who were studied psychiatrically first had 2 standard psychiatric interviews of the free-association type which eventually included a discussion of sufficient current and past material to yield data for scoring approx. 65 variables considered salient for personality evaluation. The minimum amount of time spent with and discussing each patient was 5-6 hr., and the av. was 10-12 hr. Two types of control groups were used; the first consisted of the general population, divided into normal and abnormal according to arbitarary criteria, and the second group comprised the first 74 patients admitted to the gastroenterology service while this study was in progress. No patients with large-intestine disease or regional enteritis were included. Of the 34 patients, 29 were regarded as essentially normal and 5 as abnormal; the latter included 1 or more of the following character disorders to a significant degree: indequate, infantile, passive, schizoid, depressive or dependent. There were among the normal personalities mild to moderate personality characteristics in this incidence: passive-dependent, 8; passive-aggressive, 5; and anxious, 1. Fifteen were classed as predominantly normal, i.e., to have no or very mild character disorders. There was 1 psychopathic personality who was also diagnosed as schizoid. In only 4 of 34 cases was a significant precipitating factor thought to have occurred close in time to the first attack of ulcerative colitis; in 3 cases there was a possible substantial emotional conflict. In 15 cases a moderately eventful emotional factor was present within 6 mo. of a relapse of the disease, but not before its first occurrence. In only 5 instances was a moderate-to-severe degree of stress present before the onset of the first attack of ulcerative colitis. In 9 cases a moderate-to-moderately-severe degree of stress was present before a relapse. In 14 cases, the total background, or dynamic, factors were such as to suggest the possibility of nuclear conflicts that might express themselves in somatic illness; in no case was it felt that any of the possible nuclear conflicts showed a demonstrable symbolic relation to the ulcerative colitis. No alternation of either psychiatric or physical symptoms with the ulcerative colitis was encountered in the patients' history or in their hospital course. Headaches were a complaint in 6 cases, but without significant reference to the severity of the ulcerative colitis. Mild-to-moderate depression was present in 4 cases, but there was no alternation with the symptoms of colitis. Of the 34 patients, 7 had undergone fairly extensive psychiatric treatment lasting from several mo. to 8 yr.; in 3 cases it aided the patients' adjustment to the disease, but in none did it have an appreciable effect on the course of the disease. In general, control patients showed as much psychopathology as, or more than, the ulcerative colitis patients. This series of 34 is thought to be the first in which a relatively large, consecutive and unselected group of cases has been studied by the same team, using the same methods, planned in advance.

11650 CRYTOGENETIC ULCERATIVE COLITIS AND HEMORRHAGIC RECTOCOLITIS. (Fr.) Busson, A. and J. Chomé. Arch. Mal. Appar. Dig. 56(6):563-567, 1967.

Of 78 patients, 9 had primary ulcerative cryptogenetic colitis, 64 had hemorrhagic rectocolitis (ulcerative colitis) and 5 had mixed forms. Ulcerative cryptogenetic colitis evolves in 1 or more attacks with these symptoms: a liquid diarrhea becoming purulent in 2 or 3 wk. in the absence of pathogenic bacteria; sharp abdominal pain; a variable fever occurring after some days or wk., very little bleeding; the rectum is little affected while ulcerations begin in the sigmoid and radiology reveals deep irregular folds usually in 1 segment of the colon, the site of ulceration. As the disease progresses the radiologic picture resembles that of hemorrhagic rectocolitis which arises in 1 or multiple attacks reaching the stage of irreversible lesions, the ulcerations having a spongy, striped appearance with loss of definite boundaries. Rectosigmoidoscopy showed identical lesions in the rectum (when they are present) and in the sigmoid. The mucosa is replaced by superficial ulceration or is abraded deeper than the muscularis mucosae, is marked by longitudinal bands of hemorrhagic swelling, is studded with swollen regions giving the illusion of polyps and is normal in appearance where the first 3 conditions are absent. Histologically, submucosal changes take place prior to mucosal alterations in cryptogenetic ulcerative colitis; submucosal capillaries become intensely dilated, the mucosa, congested with edema and inflammatory granulation tissue, separates from the vascular-nervous layer; extravasation of blood occurs. The desquamated regions become ulcerated. Hemorrhagic infarction, which causes death of epithelial cells is preceded by a mucous secretion due to irritation resulting in mucous abrasion (mucohemorrhagic rectocolitis) later becoming hemorrhagic rectocolitis or primary eryptogenetic ulcerative colitis. It is concluded that these are merely 2 clinical forms of the same disease, the neurovascular, physiopathological processes and reactions being identical.

11669 PANCREATOGRAPHY BY MEANS OF INTRAVENOUS ERYTHROSINE B IN CLINICAL USE. A STUDY OF THE FIRST THIRTY CASES. (Fr.) Ledoux-Lebard, G. (Fac. Med. Radiol., Paris), F. Heitz, A. Béhar, J. Rosier, L. Leger, F. Siguier and M. Prémont. J. Radiol. Electr. 48(6-7):373-378, 1967.

With this new technic the patient undergoes no more than a pneumoretroperitoneum and a pneumoperitoneum. Standard X-ray films and tomographs of face and profile are taken for reference before i.v. inj. of contrast medium; 20-30 ml of 10% erythrosine B are inj. and tomographs are taken in the same planes as the reference films, 20, 40, and 70 min. after inj. The opacity becomes apparent at 20 min., increases up to 40 min. and is attenuated or has disappeared at 70 min. The time can be determined when the differentiation in the pancreas is best as the contrast material passes into the duodenum or jejunum. Control films taken 24 hr. later as a rule show the gallbladder clearly outlined and having a slight opacity. The films taken at 40 min. usually have the clearest pictures. In the face exposure the pancreas has the form of an opaque racket, the large end latero-vertebral toward the right passing the left lateral edge of the vertebral column. This opacity is as a rule oblique below, on the right, and covers the region of the head and body of the pancreas; little of the tail is visible in this view. In profile a prevertebral opacity regularly appears in front of the prerenal border, oblique at the base and in front; here, a picture can be taken, if needed, of the head, body, or tail of the gland. If a film is taken of the long axis, with a slight modification of the face exposure, (without increase of the oblique dimension) the image of the gland shows as a prevertebral shadow, strictly vertical and in the form of a half-moon. Diagnosis of pathological conditions such as chronic pancreatitis, with and without calculi, and other morbid states can be made with this method.

11670 NORMAL DUODENAL TRYPSIN VALUES IN RESPONSE TO SECRETIN-PANCREOZYMIN STIMULATION WITH PRELIMINARY DATA IN PATIENTS WITH PANCREATIC DISEASE. (E.) Choi, H. J. (Jefferson Med. Coll., Philadelphia, Pa.), F. Goldstein, C. W. Wirts and H. Menduke. Gastroenterology 53(3): 397-402, 1967.

Pancreatic function tests were performed by analysis of duodenal-pancreatic aspirates after stimulation of the pancreas with secretin (1 clinical U/kg) and pancreazymin-cholecystokinin (75 Ivy dog U, admin. i.v.); 20 hospitalized patients (12 men, 8 women; 22-77 yr. old) without evidence of pancreatic or other organic gastrointestinal disease were used as controls; 12 patients with chronic pancreatic disease (9 [7 men, 2 women; 30-73 yr. old] with chronic or relapsing pancreatitis, 3 [1 male, 2 female; 49-69 yr. old] with carcinoma of the pancreas) were studied for comparison. Values for enzymes in normal controls after pancreozymin-cholecystokinin stimulation were as follows: trypsin, max. conc. 22.6-66.8 (mean 42.2) mg/100 ml; amylase, max. conc. 353-4457 (mean 1413) U/ml; and lipase, max. conc. 15.1-25.4 (mean 20.9) U/ml. In normals, 60-min. secretion after admin. of secretin yielded vol. of secretion of 75-339 (mean 181) ml, and bicarbonate, max. conc. 63-121.5 (mean 91) mEq/lit Among patients with chronic pancreatic disease, the mean values for bicarbonate, trypsin, lipase and amylase output were significantly lower than those of the normal group; the mean of the vol. measurements was also significantly diminished for the entire group, but was less so if the pancreatitis patients were analyzed separately from the carcinoma group. The vol. of flow show no diagnostic significance in individual patient with pancreatitis, since all but 1 patient had normal vol. of secretion. However, 2 of 3 patie with carcinoma had low vol. of secretion. It is suggested that measurements of trypsin, or of other pancreatic enzymes (amylase or lipase) may add to the accuracy and sensitivity of the secretin-pancreozymin test of pancreatic function; in view of the comparative ease and accuracy with which trypsin can be measured, it is suggested that trypsin determinations be used in clinical tests of pancreatic function, in addition to the conventional vol. and bicarbonate measurements.

11671 MEASUREMENT OF TRYPTIC ACTIVITY IN INTESTINAL JUICE AS A DIAGNOSTIC TEST OF PANCREATIC DISEASE. (E.) Cook, H. B. (Cent. Middlesex Hosp., London), J. E. Lennard-Jones, S. M. Sherif and H. S. Wiggins. Gut 8(4):408-41 1967.

The conc. of trypsin in duodenal juice, collecte by siphonage using a single-lumen tube for 4 consecutive half-hr. periods after a standardize (Lundh) test meal (containing 6% fat, 5% protein and 15% carbohydrate), was used as an index of exocrine pancreatic function. A titrimetric method was used, measuring the rate at which H ion is liberated from a substrate. The lowest coefficients of variation were found in the peak 30-min. tryptic activity and the mean 2-hr. tryptic activity after the test meal; the mean tryptic activity was the more useful measurement since it required only a single enzyme determination. The lower limit of normal using this measurement (derived from tests on 44 subjects) was found to be 9.6 µEq/min./ml. Patients presenting with pain were divided into 3 groups; those with no evidence of pancreatic disease (19 yielded no result below the lower limit of norma of 13 with possible pancreatic disease, 3 had low results (2, 8 and 8.5 µEq/min./ml). A total of 25 had proven pancreatic disease; the first 12 were studied 2 days-6 mo. after acute pancreatitis, and an abnormal result was found in only 3; an abnormal (low) result was found in 11 of the last 13 with chronic pancreatic disease. Of 16 patients with obstructive jaundice, the

tryptic activity was low in 5 of 7 who had
er of either the pancreas or ampulla of Vater;
as decreased in only 3 of 9 patients who had
ancreatic jaundice, and 2 of these had chole-
olithiasis. Patients with steatorrhea fell
4 groups; 14 of 15 with pancreatic steator-
had low mean tryptic activities; 2 with
inger-Ellison syndrome had low values (3.0
5.0 μEq/min./ml). Of 10 with nonpancreatic
torrhea, mean tryptic activity was below the
al range in 4, while in 7 patients who had
rectomy, values were extremely low in 3, and
of these, there was evidence of pancreatic
ase. This test was particularly useful in
diagnosis of pancreatic steatorrhea; the re-
s also suggest that steatorrhea occurs in
reatic disease only when the conc. of enzymes
uodenal juice falls to very low levels.

2 THE IMPORTANCE OF THE ACTIVATION AND
INACTIVATION OF PROTEOLYTIC ENZYMES FOR
IEASUREMENT OF PANCREATIC FUNCTION. (Ger.)
er-Wieland, K. (U. Hamburg, Germany) and W.
dt. Z. Gastroent. 5(4):234-238, 1967.

sin, chymotrypsin and carboxypeptidase-A conc.
determined in duodenal fluid collected in a
n. period following slow or rapid i.v. inj.
ecretin or pancreozymin. Individuals with
l pancreatic function and patients with
en pancreatic exocrine insufficiency were
ed. The values for these enzymes among
l persons did not show a distribution ac-
ng to the binomial bell curve but followed a
ithmic distribution. Patients with exocrine
fficiency showed values of only 20% of normal.
roteases were rapidly digested with or with-
he presence of Ca ions in the duodenal fluid.
ypsin inhibitors were found in the fluid.
assumed that lyosomal proteases of the in-
nal epithelium are able to hydrolyze exocrine
eatic enzymes; these cathepsins are relatively
rature-stable and are active in a pH range
7. Testing of the enzyme activity in the
nal fluid for diagnostic purposes should
re the initial reaction velocity.

3 THE TESTING OF THE PANCREAS FUNCTION
BY MEANS OF THE GLYCERINE-$^{14}C_1$ TRI-
TATE TEST. (Ger.) Uthgenannt, H. (1st Med.
, Lubeck, Germany), U. Ritter and L. Hesse.
stroent. 5(3):169-177, 1967.

rine-$^{14}C_1$-tripalmitate (20 μc/20 ml of milk)
ntubated into the duodenum of 82 patients of
30 had normal pancreas and digestive tract,
d pancreatopathies, 10 diabetes mellitus,
0 had chronic gastritis. To obtain max.
eatic exocrine secretion 0.1 mg/kg of metha-
ne s.c. and then 1.7 U pancreozymin or 1.0
retin or both as a double stimulant, were
. The intraduodenal admin. of 40 U of lipase
a second test dose of radioactive tripalmitate
e used to test absorption of fat. $^{14}CO_2$ and
ere determined in a continually-recording analyzer, CO_2 being measured by infrared absorption spectrum and the radioactivity being measured in a gas counting chamber. All calculations required are explained. The first radioactive CO_2 expired appeared between 8 and 30 min. after duodenal intubation of the test dosage. In the time interval of 60 min. and an arbitrary specific activity of 1.0 set up for the amount of exhaled radioactive CO_2, all except 3 of the 30 normal subjects attained the specific activity of 1 within 60 min.; the 3 false negatives have not been explained. Of 10 patients with pancreatic disease, (chiefly chronic pancreatitis) 9 did not show the specific activity of 1 within 60 min. and there was 1 false negative. All 10 patients with diabetes mellitus presented low specific activities. All except 1 of 10 patients with chronic gastritis showed very low values for specific activity, the other was false positive.

11674 INTRADUODENAL PRESSURES IN PATIENTS WITH BILIARY AND PANCREATIC DISEASE. (E.) Anderson, M. C. (Northwestern U. Med. Sch., Chicago, Ill.). Pacif. Med. Surg. 75(4):217-223, 1967.

Intraduodenal pressure measurements were performed in 15 patients, including 2 (1 of each sex, 50 and 58 yr. old) with no evidence of intra-abdominal disease, 6 (all female, 37-67 yr. old) with chronic biliary tract disease (5 with chronic cholecystitis, 1 of whom had a common bile duct stone, and 1 with a cystic duct remnant) and 7 (6 men, 1 woman; 28-48 yr. old) with chronic pancreatitis (in 6 of whom it was associated with excessive alcohol ingestion). Pressures were determined in the resting state, after increased intra-abdominal pressure, and after instillation of saline, dilute acid, and alkali. In normal patients, duodenal pressures increased rapidly after instillation of acid but returned to normal promptly after addition of the alkali. Patients with biliary tract disease responded in a manner similar to the controls (normal patients), except for the development of symptoms which were similar to those experienced during an attack. Patients with chronic pancreatitis exhibited marked and prolonged hypertonicity after instillation of acid into the duodenum which responded slowly to neutralization with alkali. This increased duodenal tone was accompanied by symptoms which accurately reproduced previous attacks of pancreatitis. These findings indicate that duodenal tone is increased during pancreatitis; whether this is a cause or an effect of pancreatitis remains to be elucidated.

11675 THE STRUCTURE OF TAMM-HORSFALL MUCOPROTEIN IN FIBROCYSTIC DISEASE. (E.) Friedmann, T. (NIH, Bethesda, Md.) and P. Johnson. J. Lab. Clin. Med. 70(3):404-407, 1967.

Tamm-Horsfall mucoprotein was examined by means of ultracentrifugation, starch-gel electrophoresis, end-group analysis, peptide mapping, immunodiffusion and hemagglutination. It was not possible to detect any differences in the structure of Tamm-Horsfall mucoprotein isolated from patients with mucoviscidosis compared to that from control children. Both forms were examined in the electron microscope by the method of negative staining, and their ultrastructures were not distinguishable by this technic. These results do not support the conclusion that the Tamm-Horsfall mucoprotein is abnormal in structure in mucoviscidosis. These findings are also thought to constitute strong evidence against a structural gene mutation of the protein moiety of this mucoprotein as the basis for the proposed abnormality in mucoviscidosis.

11676 STUDIES OF THE FUNCTION OF THE SWEAT GLAND, PAROTID GLAND AND THE PANCREAS IN CHRONIC BRONCHITIS AND HETEROZYGOUS MUCOVISCIDOSIS OR CYSTIC FIBROSIS. (E.) Toivonen, S. (U. Helsinki). Ann. Med. Intern. Fenn. 56(Suppl. 50):9-48, 1967.

The function of the sweat gland, the parotid gland and the pancreas were studied in 225 patients with chronic bronchitis (171 men, 54 women; 16-81 yr. old), in the parents (10) of mucoviscidotic children (definite heterozygotes), and in 126 normal controls (68 men, 58 women; 16-74 yr. old). In the sweat tests, electrolyte values higher than the normal limit (Cl conc. equal to or greater than 60 mEq/liter, Na conc. equal to or greater than 80 mEq/liter were found in 46 of 225 (20.4%) bronchitics; 4 of 126 (3.5%) normal controls had values above this limit and the difference was statistically significant. Three of 10 parents of mucoviscidotic children had above-normal values. Sex, age, and smoking had no significant effect on the findings. The sweat test was a poor heterozygote test since it revealed only a part of the heterozygotes; the i.v. aldosterone test did not improve the screening of heterozygotes. There were no significant differences between the groups in the parotid gland studies. The studies of pancreatic function, however, revealed significant findings for tryptic enzymes. The trypsin conc. in the duodenal aspirate produced by secretin stimulation was significantly lowered statistically in the parents of mucoviscidotic children; their total trypsin output and that of the bronchitic patients with high sweat electrolytes was also reduced compared with the control groups. The parents of mucoviscidotic children and bronchitics with high sweat electrolytes differed statistically from the normal control group with functional gastrointestinal complaints in the chymotrypsin control in both the conc. and total output values of duodenal aspirate. The parents of children with mucoviscidosis differed more sharply from the other groups in the fecal trypsin conc. studies, but bronchitic patients with high sweat electrolytes also had a statistically significant difference from the comparative group of bronchitics with low sweat electrolytes. No significant differences in the fecal chymotrypsin conc. were established between the adequate groups. In a comparison of all the positive findings in the sweat gland tests and parotid gland and pancreatic function studies, 3 or more positive findings out of a possible total of 9 were obtained in 9 of 10 definite heterozygotes, 14 of 19 chronic bronchitics with high sweat electrolyte values and 2 of 13 chronic bronchitics with low electroly values, and none in the patients with functional gastrointestinal complaints (normal controls). The statistically highly significant correlation obtained between the chymotrypsin conc. of duodena aspirate and stools was of general importance for adaptation of the fecal chymotrypsin determination as a screening test of pancreatic function. The correlation for trypsin was poorer, but also significant. The results for the parents of mucoviscidotic children suggest that the trypsin deficit in both the duodenal aspirate and stools distinguishes the heterozygotes better than the increase in sweat electrolytes. Although this study indicated that heterozygous mucoviscidosis may play a role in some cases of chronic bronchiti longitudinal, clinical, and comprehensive biochemical studies on large groups of definite heterozygotes are necessary for further elucidation of this point.

11677 LONG-TERM RESULTS OF NONPENETRATING PANCREATIC TRAUMA. (E.) Warren, K. W. (Lahey Clin., Boston, Mass.) and R. B. Wagner. Lahey Clin. Found. Bull. 16(2):217-223, 1967.

A follow-up study of 20 patients 2-28 yr. after blunt pancreatic trauma revealed that recurrent pseudocysts, recurrent fistulas, chronic pancreatitis, stenosis of the sphincter of Oddi and duodenal ulcer were frequent long-term complications. In total, 69 operations were performed and 9 patients required surgery for a complicatio of pancreatic trauma more than 1 yr. after the original injury. Each patient experienced at least 1 major complication of pancreatic injury; the development of an inflammatory pseudocyst was the most common (13 patients) and recurrent pseudocysts next (12 cases). The latter redeveloped after spontaneous closure of a previous internal drainage procedure in 4 cases and from unsuccessful treatment by marsupialization in 3 others. Chronic pancreatitis developed in 8 patients and 2 others had symptoms suggestive of pancreatitis. All had undergone surgery for either a pseudocyst or fistula. The interval between the trauma and chronic pancreatitis surgery ranged from 37 days to 18 yr. Some form of pancreatic resection was eventually performed in 9 cases with good or excellent results in 7 after 16 mo.-16 yr. follow-u Duodenal ulcers and intestinal obstruction each developed in 3 cases.

11678 COMPARISON OF PSYCHIATRIC SYMPTOMS IN CARCINOMA OF THE PANCREAS WITH THOSE IN SOME OTHER INTRA-ABDOMINAL NEOPLASMS. (E.) Fras I. (Mayo Clin., Rochester, Minn.), E. M. Litin and J. S. Pearson. Amer. J. Psychiat. 123(12): 1553-1562, 1967.

isefulness of psychiatric symptoms in permit-
an early diagnosis of cancer of the pancreas
eported in which 139 patients with either
ct or diagnosed cancer of the pancreas or of
olon were evaluated psychiatrically as soon
ychiatric referral was feasible. Assessment
ved psychological interviewing with special
sis on free-association response by the
nt, a general medical and psychiatric history,
ompletion of the Minnesota Multiphasic Per-
ity Inventory in most cases. Of these pa-
s, 46 were shown to have pancreatic carcinoma
4 to have cancer of the colon (control group),
the remaining patients (19) with other ill-
s formed a mixed control group. The Depres-
Rating Scale value was higher in patients
ring from pancreatic cancer. In all, 76% of
atients with proven pancreatic cancer evinced
ite psychiatric symptoms. Anxiety and
nition of serious illness were frequently
iated with the depression. Loss of ambition
stinguished from physical fatigue and a hard-
scribe "sadness" were also prevalent char-
istics. Similar findings, with the excep-
of premonition, were noted in 3 of 4 patients
proven retroperitoneal malignant lymphoma.
emaining control patients manifested a low
ence of disease-related psychiatric symptoms.
se the psychiatric symptoms appeared before
ther symptoms in almost half of the patients
pancreatic carcinoma, it is felt that initial
iatric evaluation in suspect cases of pan-
ic carcinoma may assist in differential diag-
.

98 EXCISION IN CHRONIC PANCREATITIS. (Fr.)
Mercadier, M. (Charity Hosp., Paris),
P. Clot and P. Camplez. Ann. Chir. 21(11-12):
-644, 1967.

gical management is studied in 71 cases of
onic pancreatitis involving the following 4
cedures: left pancreatectomy (32 cases);
halic pancreatoduodenectomy (21 cases); sub-
al pancreatectomy (15 cases); and repeated
createctomy (3 cases). Pain, vomiting, wt.
s, and difficulties of transit in the diges-
e tract were the chief complaints; these were
cured by surgery. Mortality due to surgery
4% while 93% of the cases were successful as
ven by subsequent examination. Severe dia-
es occurred in no case even with extensive
cedures and when the patient had already been
betic, he could be controlled with small doses
insulin. Excision of sclerosed pancreatic
enchyma is recommended for patients with
onic pancreatitis.

99 PAINLESS FORM OF CHRONIC PANCREATITIS.
(Cz.) Herfort, K. (Fac. Intern. Med.,
gue), M. Keclik and Z. Sivanova. Cesk.
troent. Vyz. 21(2):74-80, 1967.

r patients are described with the painless
m of chronic pancreatitis. These were sup-
mented with 43 patients reported in the
erature to make a group of 47, in which the
quency, sex incidence, etiological factors
clinical manifestations were evaluated and
pared with the results in 714 patients with
onic relapsing pancreatitis. The painless
m of chronic pancreatitis was found to be
atively rare, and predominates in men. With
ard to etiology, the same factors participate
development of this form as in chronic relaps-
pancreatitis; only the incidence of individual
tors was found to vary. The most frequent
m was idiopathic and alcoholic pancreatitis,
the biliary form was relatively rare. In the
ge when the painless form was fully developed
h regard to clinical manifestations, the
ncipal signs were steatorrhea, pancreatic
cifications and diabetes in various combina-
ns. In the group of patients studied, the
comitant incidence of all 3 chief signs, and
combination steatorrhea: pancreatic calci-
ation, were most frequent. The presence of
ign, steatorrhea, was less frequent in the
ge when the painless form is usually diag-
ed. With present knowledge, it is difficult
decide unequivocally whether the chronic re-
sing form and painless form of pancreatitis
etiologically 2 different types or the same
e of chronic pancreatitis which differs only
to clinical manifestations of the disease.

700 URINARY ISOAMYLASES IN THE DIAGNOSIS
OF CHRONIC PANCREATITIS. (E.) Aw, S. E.
(Roy. Postgrad. Med. Sch., London), J. R. Hobbs
and I. D. P. Wootton. Gut 8(4):402-407, 1967.

A simple method is described for the electrophoretic separation of urinary pancreatic and salivary isoenzymes of α-amylase, which offers a convenient screening test for exocrine pancreatic deficiency. Urine specimens (24-hr.) were taken from 3 groups of subjects: Group 1, 29 patients with no history or other evidence of exocrine pancreatic disease, and 5 normal subjects; Group 2, 7 cases of chronic pancreatitis and 1 patient who had total pancreatectomy for pancreatic carcinoma; and Group 3, 4 patients with diarrhea of small intestinal origin, including 3 with radiological evidence of regional enteritis, 1 patient with intestinal alactasia and 1 with gross steatorrhea who also had diabetes mellitus. None of the members of the groups had overt kidney or liver dysfunction. In Group 2, 7 of 8 patients had abnormal zymograms and low ratios, characterized by a decrease of pancreatic amylase activity in relation to the salivary amylase. The urine of patients from Groups 1 and 3 showed a preponderance of pancreatic over the salivary enzyme. The ratio of the amounts of pancreatic to salivary isoamylases in the urine is thus proposed as an index of deficient exocrine pancreatic function, and it is concluded that visual assessment of the urinary zymogram is often sufficient for a diagnosis.

11701 ACUTE RENAL FAILURE IN PANCREATITIS.
(Ger.) Creutzfeldt, W. (U. Clin.
Gottingen, Germany), F. Scheler, E. Quellhorst
and H. Schmidt. Arch. Klin. Med. 213(3):197-
218, 1967.

Of 300 patients treated for renal failure, 14 had renal disease ascribed to pancreatitis; 7 of these 14 died of acute renal failure. Seven additional cases of acute pancreatitis were discovered among 26 with acute renal disease despite the lower incidence of kidney conditions in the last few yr. In 8 patients there were no characteristic symptoms of pancreatitis at the onset of renal failure; elevated serum aymlase was found in 4; this elevation usually decreased with progression of the disease; elevation of urine amylase was never noted after onset of the acute kidney condition. Transient hyperglycemia occurred in 5 patients. In 9 of 10 patients the serum Ca conc. decreased at onset of acute renal failure; hypocalcemia was most marked in those patients who died. In 4 cases the diagnosis was made at autopsy. A pancreatic pseudocyst developed in 3 subjects. Therapy consisted of 35 hemodialyses or peritoneal dialyses. Death was due to circulatory collapse; 9 patients showed circulatory shock lasting from 1-24 hr. at the onset of renal failure due to pancreatitis. The timely and adequate treatment of hypovolemic shock is of primary importance. Because plasma protein loss causes loss of fluid and, consequently, hemoconcentration, the i.v. replacement of H_2O, electrolytes and albumin assures a normal circulatory function. Prognosis may be improved by early peritoneal dialysis.

11702 EXPERIMENTAL TRYPTIC PANCREATITIS THROUGH METABOLIC LESIONS. SEROLOGICAL, HISTOLOGICAL AND ELECTRON MICROSCOPE INVESTIGATIONS.

(Ger.) Kössling, F. K. (Johannes Gutenberg U., Mainz, Germany), M. Nagel and A. Schäfer. Z. Gastroent. 5(3):158-168, 1967.

Pancreatitis was induced in 18 dogs (20 kg wt.) by ligation of the main pancreatic duct, the i.v. inj. of secretin (1 U/kg), and the intra-arterial inj. of 5 ml of Na malonate. Seven dogs developed acute and subacute pancreatitis and died within 60 hr.; 5 developed chronic pancreatitis; 2, subacute and acute. Trasylol treatment was given to 4 chronic dogs. Three other dogs, 1 with ligation of the main pancreatic duct and i.v. inj. of secretin, and 2 with intra-arterial malonate inj. served as controls. Blood tests (as enzyme conc.) were performed on all animals to determine the intensity of the pancreatitis. Tissues were taken for histologic and ultramicroscopic examination. The electron microscope showed a decided pericapillary and interstitial edema in the acute stage. The cisterna of the endoplasmic reticulum were enlarged; ribosomes were markedly thickened; the zymogen granules seemed increased in number; mitochondria, relatively few in number, had increased matrix with fewer cristae, and there were indications of necrobiosis. Dissolution of fine submicroscopic membrane structures followed and endoplasmic reticulum and mitochondria became vacuolated. Conc. of the ground plasma, fat droplets, and lipoprotein structures were observed. All experimental animals presented a severe hemorrhagic pancreatitis. In the control with secretin inj. and duct ligation a mild, chronic, nontryptic pancreatitis ensued. Malonate inhibited the succinic dehydrogenase thus lowering the resistance and leading to autodigestion of the pancreas by pancreatic proteolytic enzymes. It is concluded that the pathogenic effect of bile reflux consists only of ductal high pressure with ensuing edema of the ductal system. Proteolytic enzymes do not require bile for activation.

11703 GALACTOSE-INDUCED PANCREATIC DYSTROPHY OR PANCREATITIS--HISTOLOGIC, HISTOCHEMICAL AND ELECTRON MICROSCOPIC STUDIES.

(Ger.) Putzke, H. P. (U. Rostock, Germany) and A. Bienengräber. Beitr. Path. Anat. 135(3):333-349, 1967.

D-Galactose was fed to 40 rats (150 g wt.) in a diet at a rate of about 5 g day while 30 other rats received D-galactose 1, 1.5 or 2 g/day by i.p. inj. in 50% soln. Galactose admin. was for 5-10 days. Pancreatic tissue was fixed for histochemical tests and ultramicroscopy. The animals fed galactose in the diet were little affected by the sugar; however, those rats which received the sugar i.p. were apathetic and showed loss of wt. About 33% had pale, grayish-yellow pancreati glands; histologically, 66% of the animals had damage to the exocrine tissue of the gland. The acini showed increased secretion granules and tightly-packed acidophil granules in the epithelial cells; the tryptophan reaction was intensified. The ground ergastoplasm seemed to be compressed and the cytoplasmic RNA was reduced. Vacuoles which were present in the basal zone of the cells seemed empty or else they contained eosinophil or strongly-basophilic material. Some nuclei were pyknotic and some acini showed total degeneration. The lumina of intralobular ducts were almost free of secretion. After 10 days of treatment lymphocytic and fibroplastic cells attracted by the inflammation were present in some lobules where the secretory parenchyma had been lost; other undamaged lobules showed acinar epithelium in the stage of completed synthesis or the stable phase. The effect of galactose on the enzyme content was relatively small. The glandular areas with increased secretion granule had greatly enhanced enzyme activity of unspecified esterase and to a somewhat lesser degree of lipase and amylase; alkaline phosphatase, cytochrome oxidase and succinic dehydrogenase were easily activated. In varying degrees these effects were also true for other enzymes. The electron microscope showed degradation of the cytoplasm (with excess secretory granules), fewer mitochondria with increased matrix, and damaged cristae in the degenerating lobules. Membrane structures were abnormal. Infiltration of inflammatory cells indicated pancreatitis.

11704 PERITONEAL DIALYSIS IN PANCREATITIS IN DOGS.

(E.) Cuello, L. (U. Puerto Ric Sch. Med., San Juan), E. Vásquez, R. Rios, V. Gutiérrez and F. L. Raffucci. Bol. Asoc. Med. P. Rico 59(6):237-242, 1967.

Fatal hemorrhagic pancreatitis was produced by autologous bile admin. in dogs, which were then divided into 6 experimental groups. One group constituted untreated controls, while the remaining 5 groups were treated with peritoneal dialysis and normal saline (0.75 ml kg/hr.) and/or antibiotics (chloromycetin, 100 mg; penicilli 400,000 U) and atropine (grains 1/150). Peritoneal dialysis was initiated 1 hr. after release of arterial occlusion and maintained until the dog expired. The lowest degree of hemoconcentration was observed in dogs given dialysis ther Elevated preoperative serum amylase levels were affected by dialysis in any group. Increased survival time, which was statistically significa was noted in treated dogs as compared to control dogs. Blood sugar levels progressively increase in all 6 groups with the highest levels associat with the longest survivors in the last 2 treated groups. At autopsy, dogs treated by dialysis ma fested only a minimal peritoneal reaction. Thes data encourage the use of peritoneal dialysis as

adjunct to antibiotic, anticholinergic and elec-
trolyte soln. therapy in the early phase of
treating severe pancreatitis.

11705 HEPATIC LESIONS IN ACUTE EXPERIMENTAL
PANCREATITIS IN DOGS. (Pol.)
Tyszkiewicz, S. (Inst. Path. Anat., Acad. Med.,
Bialystok, Poland) and E. Bernacki. Acta
Physiol. Pol. 17(3):403-415, 1967.

The effect of acute pancreatitis on the histo-
athologic changes in the liver was studied in
31 dogs of both sexes (av. wt. 15 kg). In each
log, 7 ml of bile, incubated with 20 mg of
crystalline trypsin, was inj. into the main pan-
creatic duct. Thirteen dogs (Group 1) died from
acute hemorrhagic pancreatitis within the first
24 hr. The remaining dogs received parathyroid
ormone (Parathormone; 6 U/kg body wt./day) which
ept them alive. Acute necrotic pancreatitis
as observed in 13 dogs which were sacrificed
fter 4 days (Group 2). The remaining 5 dogs
ere sacrificed between day 14 and 42 (Group 3)
o determine the effect of time on liver changes
uring acute pancreatitis. The extensive patho-
ogic changes in the liver were proportional to
he intensity of the inflammatory process in the
ancreas and were less pronounced in Group 2 than
n Group 1. The changes included parenchymatous
nd vacuolar degeneration and fatty infiltration
f liver cells, diminished glycogen content and
ascular lesions. The epithelial cells of the
ile duct were enlarged, causing occlusion of the
maller ducts and cholestasis. The liver capsule
as stretched, thickened, and infiltrated with
BC and lymphoidal cells. Cytoplasm of the liver
ells contained bile pigment and hemosiderin.
he lumen of the sinusoids was enlarged where
iver cells were small, but narrow and sometimes
ompletely closed where the cells were swollen
nd degenerated. In Group 3 there was an increase
f collagen and argentophilic fibers in the portal
paces, periphery of the lobules and sometimes
ithin the lobules. It is concluded that dogs who
urvive acute pancreatitis show permanent changes
the liver which are characteristic of the
itial phase of liver cirrhosis.

1706 EXPERIMENTALLY INDUCED ACUTE HEMOR-
RHAGIC NECROSIS OF THE PANCREAS FOLLOW-
NG GASTRECTOMY ACCORDING TO BILLROTH II. (Pol.)
owiński, W. (1st Surg. Clin., Warsaw). Pol.
zegl. Chir. 39(6):561-568, 1967.

total of 35 dogs (8-20 kg) were divided into 4
oups. In Group 1 (22 dogs) a closed duodenal
op, 10-15 cm long, containing both openings of
e pancreatic ducts was created. The continuity
the alimentary tract was maintained by con-
cting the stomach to the efferent segment of
e duodenum. In Group 2 (4 dogs) a partial gas-
ectomy according to Billroth II was performed
d an occlusion was created by binding off the
ferent loop with tape. In Group 3 (5 dogs)
ter partial gastrectomy according to Billroth
different degrees of obstruction were obtained
by constriction of the efferent loop (diameter: 10 mm, 8 mm, 6 mm and 4 mm.). Group 4 (4 dogs) having undergone partial gastrectomy only, served as controls. In a few dogs of Groups 1 and 2 a Ba suspension was left in the duodenal loop and later on radiographic examination showed $BaSO_4$ grains in the lumen of the pancreatic ducts and destroyed parenchyma of the pancreas. Diastase examination of the blood, fluid from abdominal cavity, and fluid from the duodenal loop showed an increase of the diastase levels and an increase in the proteolytic activity. All dogs died or were sacrificed within 48 hr. after surgery and histopathologic examinations revealed acute hemorrhagic necrosis of the pancreas in dogs of Group 1 which was probably due to the emptying of duodenal contents into the pancreatic ducts. Dogs of Group 2 had somewhat less severe pathologic changes probably due to a longer duodenal loop. Changes in dogs of Group 3 were more of an inflammatory than a necrotic nature and were more severe with a greater constriction of the lumen. It is suggested that 1 of the causes of acute hemorrhagic necrosis of the pancreas in patients after gastrectomy is the regurgitation of duodenal contents into the pancreatic ducts.

LIVER AND BILIARY TRACT
GENERAL

1719 ACTIVITY OF SERUM AMINOPEPTIDASES IN
DISEASES OF THE LIVER AND BILE DUCTS.
E.) Szczeklik, A. (3rd Dept. Intern. Med.,
roclaw, Poland). Acta Med. Pol. 8(1):1-25,
967.

ne presence in human serum of peptidase activities
oward 2 new synthetic substrates, α-D,L-
spartyl-p-nitroanilide and glycyl-p-nitroanilide,
as established, and the activity of both
ubstrates was compared with serum γ-glutamyl
ranspeptidase and leucine aminopeptidase
ctivities in healthy subjects as well as in
atients with hepatobiliary disorders. Human
erum exhibited enzymatic activites toward
oth of these substrates that differed in some
ochemical and clinical aspects from serum
nzymatic activities toward L-leucyl-β-naphthyl-
nide and γ-L-glutamyl-p-nitroanilide. An
ncrease of activity toward all 4 substrates was
ound in a high percentage of cases with
epatobiliary diseases, thus making the determina-
on of these activities useful in clinical
agnosis. Changes in γ-glutamyl transpeptidase
ctivity and in glycyl-p-nitroanilide splitting
ctivity appeared to be more sensitive liver
unction tests than the estimation of serum
ctivity toward L-leucyl-β-naphthylamide and
D,L-aspartyl-p-nitroanilide. Obstructive
undice, cancer of the liver and biliary
rrhosis were accompanied by higher elevation
peptidase activities toward all 4 studied
bstrates than viral hepatitis, portal cirrhosis
d cholecystitis without jaundice. Normal
D,L-aspartyl-p-nitroanilide-splitting activity
serum, in the presence of a marked elevation
the other peptidase activities, is suggestive
liver cancer. Leucyl, aspartyl and glycyl
inopeptidase activities exhibited a decline
hepatic coma several days before death.

1720 pH AND CONCENTRATION OF PANCREATIC
ENZYMES IN ASPIRATES FROM THE HUMAN
ODENUM DURING DIGESTION OF A STANDARD MEAL
PATIENTS WITH BILIARY OR HEPATIC DISORDERS.
.) Worning, H. (Blegdams Hosp., Copenhagen),
Müllertz, E. H. Thaysen and H. O. Bang.
and. J. Gastroent. 2(2):150-156, 1967.

a series of patients comprised of 34 (5 men,
women) with anicteric biliary diseases
hose with gallstones and patients subjected
cholecystectomy), 20 (6 men, 14 women) with
structive jaundice (these had common bile
ct stones) 8 (4 men, 4 women) with hepatic
rrhosis (portal or biliary cirrhosis) and 3
men, 1 woman) with hemochromatosis, the
testinal contents were aspirated in 4
bsequent periods of 20 min. each after ingestion
a standard meal. The vol., pH and conc.
α-amylase, trypsin, chymotrypsin and lipase
re determined in the collections. The conc.
the different enzymes remained unchanged
roughout the period of aspiration in the groups of patients studied; the conc. in female and male patients were identical in all groups of patients. The conc. of lipase was more markedly reduced than the conc. of amylase and of trypsin in patients with anicteric biliary diseases and in patients with hepatic cirrhosis. Conc. of enzymes below the lowest normal value throughout the period of digestion represented an uncommon finding. Low conc. of amylase were noted in the 3 patients with hemochromatosis. The exocrine pancreatic function, it is concluded, is rarely found to be reduced in patients with biliary or with hepatic disorders.

11721 HEPATIC-ARTERY LIGATION FOR HEPATIC HEMANGIOMATOSIS. (E.) DeLorimier, A. A. (U. California Sch. Med., San Francisco), E. B. Simpson, R. S. Baum and E. Carlsson. New Eng. J. Med. 277(7):333-337, 1967.

Hepatic capillary hemangioma, like cutaneous hemangioma, is characterized by rapid progression in early infancy, followed by involution. When involuting hepatic hemangiomas are symptomatic, they diffusely involve the liver and produce arteriovenous shunts and high-output heart failure; the triad of multiple enlarging cutaneous hemangiomas, hepatomegaly and congestive heart failure follows. In all but 2 of the 25 cases reported since 1932, high-output congestive heart failure developed due to a large hepatic arteriovenous shunt through the tumor in the liver; 22 of the 25 patients with high-output heart failure died. In the present case, a baby girl with conventional hepatic hemangioma pathology, the hepatic artery was ligated at its origin from the celiac artery, proximal to the right gastric and gastroduodenal branches, in order to diminish the large hepatic arteriovenous shunt; this relieved the high-output heart failure and the patient recovered. This is the first reported case in which this technic was used for treatment of hepatic hemangiomatosis.

11722 DETERMINATION OF FATTY ACID AND TRIGLYCERIDE TURNOVER IN THE PLASMA OF MAN UNDER NORMAL AND PATHOLOGIC PHYSIOLOGICAL CONDITIONS. (Ger.) Sandhofer, F. (U. Clin. Innsbruck, Austria). Wien. Z. Inn. Med. 48(5)(Suppl.):1-32, 1967.

Both the single inj. and the infusion methods of admin. of tritiated palmitic acid were used to study the quantitative turnover rate of free fatty acids and triglycerides in the plasma; both methods gave comparable results. Measurements of radioactivity were made in a liquid scintillation counter after peparation of the fatty acids, triglycerides and other lipid fractions by thin-layer chromatography. The conc. of fatty acids, triglycerides, rate of incorporation of radioactive fatty acid into triglycerides, the blood sugar level, and the blood cholesterol conc. were all determined. These tests were conducted on 11 normal subjects, on 6 with essential hyperlipemia, 5 with symptomatic hyperlipemia, 7 with liver cirrhosis, 5 with hyperthyroidism, and 11 with diabetes mellitus. In essential hyperlipemia the formation of plasma triglycerides was moderately increased but the chief cause for the excessive accummulation of plasma triglycerides was the diminished removal of triglycerides from the blood. In liver cirrhosis, especially decompensated cirrhosis, only a small amount of fatty acids were incorporated into plasma triglycerides despite high conc. of free fatty acid in the arterial blood; this could have been due to a defect of liver cell function and/or disturbed hepatic circulation. Among patients with hyperthyroidism, the turnover of free fatty acids in the plasma was increased; the free fatty acids were rapidly oxidized and were esterified to triglycerides only in small quantities. In diabetic decompensation as well as in cases of low blood sugar values, free fatty acids were utilized for energy and the synthesis of triglycerides was diminished. With a blood sugar level of about 200 mg% in spite of low fatty acid turnover, the greatest rate of triglyceride synthesis was observed.

11723 LIPOPROTEIN LIPASE ACTIVITY, SERUM LIPIDS, AND THE HEPARIN EFFECT UPON BLOOD SUGAR LEVEL IN ATROPHIC LIVER CIRRHOSIS AND CHRONIC HEPATITIS.

(Ger.) Bosadjiewa, E. (Med. Inst., Varna, Bulgaria), G. Warbanow, S. Markowski, L. Beltschew and E. Russinow. Z. Ges. Inn. Med. 22(13):393-396, 1967.

Twelve patients with atrophic liver cirrhosis, 8 with chronic hepatitis, and 17 healthy persons each received a morning, fasting, i.v. drop infusion of 500 ml saline soln. containing 150 mg heparin in 4 hr. Before and after the infusion, blood sugar levels, free serum heparin, and serum lipids were determined; in the lipid fraction cholesterol, phospholipids, β-lipoproteins, unesterified fatty acids and triglycerides were measured as well as serum lipoprotein lipase activity. The total lipids and the β-lipoproteins were lower in cirrhotics than in normal subjects and the lipoprotein lipase and free heparin were higher. Among those with chronic hepatitis only free serum heparin was elevated while all other factors were normal. The differences between the cirrhotics and the patients with chronic hepatitis were statistically significant, even the serum heparin conc. which was greater in cases of hepatitis than cirrhosis. The infusion of 150 mg heparin in normal subjects caused a statistically significant increase of unesterified free fatty acids, free heparin, and recalcification time. In cases of hepatitis, a statistically significant decrease of cholesterol, total lipids, triglycerides and β-lipoproteins occurred and a significant elevation of unesterified fatty acids, free heparin and recalcification time also took place. The correlation between the elevation of blood sugar produced by heparin and the decrease of β-lipoprotein in the cirrhotics and the diminished cholesterol and β-lipoprotein in chronic cases of hepatitis was significant. No such correlation between the normal and cases of chronic hepatitis was found. A significant correlation among increased sugar levels due to heparin and the elevation of free fatty acids and serum heparin within the group of cirrhotics was observed.

11724 THE PRESSURE-VOLUME DIAGRAM AND ELASTICITY OF THE TOTAL LIVER VASCULAR SYSTEM OF THE CAT IN SITU.

(Ger.) Lutz, J. (U. Wurzburg, Germany), U. Peiper, J. Segarra-Domenech and E. Bauereisen. Pflueger Arch. Ges. Physiol. 295(4):315-327, 1967.

Anesthetized cats (14) were studied during elevation of hepatic venous blood pressure by perfusion at a constant rate of flow by the hepatic artery and/or the portal vein. The animals were heparinized and blood from the aorta was passed through a regulating pump into the cannulated hepatic vessel, or the vessel was perfused from an oxygenated reservoir of diluted beef blood warmed to 38°C. The measurements made were the venous pressure in cm H_2O (the variable factor which could be altered by changing the hydrostatic pressure of the perfusion fluid) and the vol. outflow from the system was recorded by an electric-drop counter. A number of other factors were considered; the effect of the rate of flow upon the size of the drops, and the action of increased venous pressure (e.g., from 3-6 cm H2O) in causing a period of variable drop rate prior to a steady state. Pressure-vol. curves in most cases showed a convexity toward the vol. axis, but in some there was a sigmoid shape. From these data are derived: storage vol. (3.78 ml/kg); vol. elasticity $E'=\frac{\Delta p}{\Delta V}$ (slope) = (2450 dynes cm^{-5}/kg); and compliance (2.42 ml/mmHg x 100g of tissue). The liver represents 12.5% of the estimated distensibility of the entire blood-vascular system. These factors are based on a venous pressure range of 0-9 cm H_2O.

11725 MEASUREMENT OF THE SIZE OF THE LIVER IN THE NEWBORN: A RADIOGRAPHIC ESTIMATE.

(E.) Howie, R. N. (U. Auckland, New Zealand). Aust. Paediat. J. 3(2):113-118, 1967.

Over a 12-mo. period, 492 chest radiographs were taken of 205 newborn babies, premature and fullterm; these included 178 babies with variety of respiratory disorders, 12 normal abies and 15 with symptoms of asphyxia at birth it who subsequently had no respiratory fficulties. Forty % of the films were taken the first day of life, and the remainder to the age of 2 mo. Measurements of its ickness were made in films which included e liver area and in which an apparent outline the liver could be seen; an oblique line was awn along the presumed liver edge and a rallel line drawn at a tangent to the right aphragm. The distance (m) at right angles etween these lines was measured in cm. Measure- nts on the radiographs were related to the . of the liver recorded at necropsy in 22 bies who died within 24 hr., and in a further who died within the following 12 mo. The tline of the liver was not included in 51 of e 492 radiographs; in the other 441 films, gas the intestine and air in the lungs outlined e liver shadow in 307 (69.6%). There was a asonably close correlation between the wt. the liver in g and the cube of the thickness the liver in cm (m^3) to the extent that the . could be predicted from the formula: ver wt. (g)=0.85 m^3 + 19.2. In some babies, duly small or large amounts of intestinal s influenced the apparent size of the liver d therefore the estimation of its wt.; when cessive amounts of gas were present, the liver peared deceptively small. In 25 babies, 3 more radiographs of the chest were taken ring the first 2 wk. of life; there was no ange in liver size in 17 babies, including with the idiopathic respiratory distress ndrome; in 1 there appeared to be a consistent crease in size, in 4 a consistent diminution d in 3 cases an apparently random variation, obably due to variations in the amount of imentary gas. This method appears to be eful, within limits, in estimating the size the liver in the living infant. The amount intestinal gas present, if excessively unduly small, influences the estimation liver size.

1726 SERUM MUCOPROTEIN LEVELS IN AMOEBIC LIVER ABSCESS. (E.) Ruas, A. Inst. Med. Res., Lourenco Marques, Mozambique) d R. Nunes De Almeida. Ann. Trop. Med. rasit. 61(1):21-25, 1967.

e correlation between serum mucoprotein values d certain pathological conditions would pear to offer a potential method for the iagnosis of these conditions. Nothing in the iterature has been found that would relate rum mucoprotein content and amoebic liver scess. In this study the serum mucoprotein vel of 61 adult male patients with a confirmed iagnosis of this condition was found to be ignificantly elevated. The fact, however, at an elevated serum mucoprotein level is countered in a variety of diseases does not ke this determination especially useful in the agnosis of amoebic liver abscess. It has oved helpful in the differentiation of amoebic liver abscess and primary carcinoma of the liver, in which the serum mucoprotein level is not elevated in all instances. In those cases in which the level was elevated the rise was moderate whereas in amoebic liver abscess the elevation is characteristically high. The addition of the serum mucoprotein level determination to the usual indices of diagnosis of amoebic liver abscess (symptomatology, radiology and liver puncture) should be useful in future diagnostic procedures.

11727 AN ELECTRON MICROSCOPIC STUDY OF THE LIVER PARENCHYMA AND SCHISTOSOME PIGMENT IN MURINE HEPATOSPLENIC SCHISTOSOMIASIS MANSONI. (E.) Stenger, R. J. (Western Res. U. Sch. Med., Cleveland, Ohio), K. S. Warren and E. A. Johnson. Amer. J. Trop. Med. 16(4):473-482, 1967.

Overt hepatosplenic schistosomiasis developed in mice after their exposure to cercariae of a Puerto Rican strain of Schistosoma mansoni. After 8, 11, 33 and 52 wk. of infection, livers of the mice were prepared for light and electron micrscopic study. During all intervals, randomly-observed and periportal parenchymal cells exhibited ultrastructural integrity. In the early stage of the disease, paragranuloma hepatocytes displayed subcellular alterations indicative of hepatocellular injury, but at late intervals, paragranuloma hepatocytes revealed no major ultrastructural abnormality. These observations provided further evidence that toxic factors from adult schistosome worms do not adversely affect the hepatic parenchyma. The ultrastructural data corroborated previous evidence indicating that the schistosome ovum is the primary factor in the pathogenesis of overt hepatosplenic Schistosomiasis mansoni. The electron-microscopic study revealed the schistosome pigment as comprised of intensely osmiophilic, very dense, ovoid and doughnut-shaped structures. In this form, the pigment was observed in Kupffer's cells along the hepatic sinusoids and in the phagocytic cells of the hepatic granulomata.

11728 EFFECTS OF A TREATMENT WITH COENZYME A, α-LIPOIC ACID, DIPHOSPHOPYRIDINE NUCLEOTIDE AND COCARBOXYLASE ON ENDOGENOUS HEPATIC COMA. (E.) Thölen, H. (Med. U. Clin., Basel, Switzerland), A. Colombi, F. Duckert, F. Huber, H. R. Müller and F. Bigler. Helv. Med. Acta 33(6):492-504, 1967.

A total of 20 patients with disturbances of consciousness due to the following diagnosis were treated: hepatitis, 15 (acute necrosis of the liver in 6), purulent cholangiohepatitis, 1 and intoxication with Amanita phalloides, 1. The patients were treated with i.v. infusions of coenzyme A, α-lipoic acid and diphosphopyridine nucleotide; supplements of cocarboxylase were given in 16 cases. Usually 240 mg coenzyme A (75-80%) and equimolar quantities of α-lipoic acid, diphosphopyridine nucleotide and cocarboxylase, dissolved in isotonic glucose or saline (240 ml), were admin. (1 ml/min.) daily. The treatment was successful in 15 of 20 cases; 7 of the 15 successfully-treated patients demonstrated severe disturbances of consciousness. In most cases, mental improvement occurred between the second and fourth day of treatment. Three of 5 unsuccessfully-treated patients were admitted to the hospital in a terminal stage, had total necrosis of the liver and died during or immediately after the first infusion. After treatment pyruvic acid, acetoin, 2,3-butylene glycol or acetoin-2,3-butylene glycol conc. in blood showed a diminution in 66% of all cases. In most cases Quick values and coagulation factors rose during treatment. Hypalbuminemia was corrected in 4 of 6 patients; of 8 patients with hyper-γ-globulinemia, 5 had normal and 3 nearly normal γ-globulin values after treatment. During treatment blood ammonia levels were measured in 14 patients, with a decrease in 11 and an increase in 2. Immediately after treatment, a decrease of serum bilirubin (15 of 17), SGOT (13 of 14), SGPT (17 of 17) and serum Fe (6 of 7) was observed. Of the 15 patients with decreased serum bilirubin, 11 had an increase of short duration initially during treatment. Patients in whom disturbances of consciousness had disappeared before liver biopsy, still showed remarkable pathologic changes of the liver. In 10 patients with repeated liver biopsies, the final biopsy was nearly normal.

11729 IMMUNOLOGY IN CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (Ger.) Kinda, K. (Petrosu Hosp., Moinesti, Rumania). Z. Ges. Inn. Med. 22(14):430-432, 1967.

The following tests were carried out in 25 patients with chronic hepatitis: (1) Thymol, (2) Kunkel's, (3) Huerga-Popper's, and (4) Huerga-Popper's with the following modifications: inactivation of C'_1 and C'_2 fractions of the complements by heating to 56°C for 1 hr.; inactivation of C'_2 fraction by heating to 50°C for 0.5 hr.; inactivation of the C'_3 fraction by zymosan; and inactivation of the C'_4 fraction by NH_3. Inactivation at 56°C for 1 hr. or at 50°C for 0.5 hr. yielded exactly the same numerical values in the Huerga-Popper test as in Kunkel's. The $SH_2 \rightleftarrows S{=}S$ reaction becomes irreversible with heat, S=S being the stable configuration. This was investigated further in 9 cases of compensated and decompensated liver cirrhosis; when decompensation was extreme the values of the Huerga-Popper reaction reached the values of the Kunkel test. The titer of C_2 (the main fraction of the complement) was studied by means of hemolytic reactions in the group of patients with compensated and varying degrees of decompensated liver cirrhosis and in 9 healthy controls. The cirrhotics had much weaker titers of C_2 than the normal; 1 of the completely decompensated ones showed no titer and the other showed the weakest perceptible titer. It is suggested that this technic might be a measure of functional damage in the liver.

11730 BROAD-BAND HYPERGAMMAGLOBULINEMIA AND CHRONIC LIVER DISEASE. I. DIAGNOSTIC AND PROGNOSTIC MEANING OF THE ELECTROPHORETIC PATTERNS. (E.) Bonomo, L. (U. Bari, Italy) and U. Gillardi. Acta Hepatosplen. (Stuttgart) 14(3):142-151, 1967.

A total of 286 electrophoretic patterns with broad-band mountain-like hypergammaglobulinemia were studied; these were obtained from 162 patients with various liver disease states (liver cirrhosis, 86; progressive chronic hepatitis, 34; infectious hepatitis, 4; cardiac cirrhosis, 15, and other chronic liver diseases such as alcoholism, 23) and 124 with nonliver disease states (chronic bronchitis, 33; connecti tissue disease, 24; chronic brucellosis, 6; chronic kidney disease, 10; lymphomatous and blood diseases, 14; and miscellaneous, 37). Such hypergammaglobulinemia patterns were divide into 3 types according to the degree of hypergammaglobulinemia and its extension into the β- and α-region with bridging, e.g., loss of demarcation between the β- and γ-globulins. The A pattern was characterized by the evident increase of the γ-globulin fraction which showed a mountain-like peak; it was usually much broade than steep and distinctly separated from the β-globulin peak. The B-pattern was characterize by the occurrence of β- γ-bridging; the shape of the γ-globulin peak was broader and in some cases steeper than the A type. The C pattern more evidently showed the β- γ-bridging; there was a huge γ-globulin peak which extended into the β-globulin area; its ascending branch did not show a clearcut origin but actually began in the β and often the α_2-globulin area; the albumin level was at the lower limits of normal. The A pattern, which showed the less-marked alterations, was mostly found in cases with various non-liver diseases (which accounted for 72% of such patterns). Of the B patterns, which showed more marked alterations, 60% occurred in liver disease states; however, other disease conditions were frequently associated with this type of pattern (connective tissue diseases, chronic bronchopulmonary disease, and others). The C pattern, which had the most severe alterations, occurred predominantly (in 81.9% of the cases) in liver cirrhosis, mostly in the post hepatic type of liver damage; 6.5% of such patterns belonged to patients with connective tissue diseases. Some relationship appeared to exist between the etiopathogenesis (alcoholic or post hepatic) of liver disease states as estimated by the history as well as by histopathological data, and the 2 most severe types (B and C) of mountain-like hypergammaglobulinemic patterns. Therefore these features of hypergammaglobulinemia appear to bear diagnostic and prognostic implications.

731 BROAD-BAND HYPERGAMMAGLOBULINEMIA
AND CHRONIC LIVER DISEASE. II.
MUNOGLOBULIN LEVELS IN LIVER CIRRHOSIS. (E.)
nomo, L. (U. Bari, Italy) and U. Gillardi.
ta Hepatosplen. (Stuttgart) 14(3):152-156,
67.

e levels of the 3 classes of immunoglobulins,
A, and M, were determined in 51 sera from
tients with broad-band hypergammaglobulinemia,
d the possible relationships between the
munoglobulin levels and the clinical diagnosis
d stage of the liver disease were studied.
addition, serum levels of the 3 immunoglobulins
re estimated in patients with post-hepatic or
e alcoholic type of liver cirrhosis. Of
e sera studied, 10 (4 from patients with
ronic bronchitis; 6 from chronic hepatitis
tients) showed an A-pattern, 10 a B-pattern
d 31 a C-pattern (the last shows the most
vere degree of hypergammaglobulinemia and
γ-bridging). All 41 exhibiting the B and
patterns belonged to patients with liver
rhosis. A post necrotic pattern prevailed
on biopsy study in all 16 cases of post hepatic
rrhosis so-studied, whereas a portal pattern
s observed in all 5 cases of clinically-diag-
sed alcoholic cirrhosis who were studied by
opsy. The quantitative evaluation of the
mmunoglobulins was carried out by means of
gel diffusion technic incorporating the
ecific antisera into the agar. A progressive
crease of the immunoglobulin A fraction was
und in parallel with the increase of the β-
ridging phenomenon in the electrophoretic
ttern. In parallel with the increase of the
munoglobulin A fraction, there was also a
ogressive increment in the immunoglobulin M
ction, particularly in patterns of the C
pe. The most marked increments of the
munoglobulins A and M fractions were found
the post hepatic type of liver cirrhosis, in
reement with the predominant incidence of the
pattern in this type of cirrhosis. The
umin fraction was also significantly lowered
this type of cirrhosis.

32 OBSTETRIC CHOLESTASIS AND PRURITUS
OF PREGNANCY. (E.) Kater, R. M. H.
y. Prince Alfred Hosp., Sydney, Australia)
S. P. Mistilis. Med. J. Aust. 1(13):638-640,
7.

tudy of liver disease in pregnancy and
ritus of pregnancy was initiated to determine
incidence of obstetric cholestasis and
relationship of this entity to pruritus
pregnancy. A total of 42 women were found
have liver disease out of 8810 confinements
r a 2-yr. period. Obstetric cholestasis
ich was not previously reported in Australia)
the most common liver disorder, being
sent in 12 of the 42 cases, and also the
t common cause of jaundice during pregnancy.
tetrical cholestasis was characterized by a
d degree of jaundice and severe pruritus in
the third trimester with rapid spontaneous resolution after delivery, marked elevation of the serum alkaline phosphatase and specific liver phosphatase levels, and canalicular cholestases out of proportion to the degree of hyperbilirubinemia on light microscopy. Pruritus of pregnancy was also common. The identical episodes of pruritus, which ofter recurred in subsequent pregnancies, the comparable elevation of the serum alkaline phosphatase and specific liver phosphatase levels, and the similar changes on light microscopy from aspiration liver biopsy sections, suggested that pruritus of pregnancy and obstetrical cholestasis are merely clinical variants of an identical liver disorder. The dilatation of the bile canaliculi, and the swelling and distortion of the microvilli on electron microscopy in a case reported in this series, appear to point to an excretory defect at this level in the parenchymal cell. The rapid relief of cutaneous itching in 4 patients given cholestyramine p.o. suggested that the pruritus of these 2 disorders was due to reduced liver excretion of bile salts.

11733 HYPERBILIRUBINEMIA: SIGNIFICANCE OF
THE RATIO BETWEEN DIRECT-REACTING
AND TOTAL BILIRUBIN. (E.) Fevery, J. (St.
Raphael Acad. Hosp., Louvain, Belgium),
J. Claes, K. Heirwegh and J. De Groote.
Clin. Chim. Acta 17(1):73-79, 1967.

Direct-reacting and total bilirubin were determined in sera from patients with obstructive jaundice, hepatitis and cirrhosis by 3 different methods. Basically the same results were obtained using the method of Jendrassik and Cleghorn (modified) and the method of Weber and Schalm; the former had the advantage of greater simplicity. Results obtained with the method of Ducci and Watson showed somewhat greater scattering. With these 3 methods, a linear relationship was found between direct-reacting and total bilirubin in cirrhosis, hepatitis and obstructive jaundice (intra- and extrahepatic). Using the methods of Jendrassik and Cleghorn, and of Weber and Schalm, an identical regression coefficient was observed for the different groups examined. This relationship was characteristic for so-called postmicrosomal icterus. In contrast, the premicrosomal and microsomal jaundice (increased production, reduced hepatic uptake or conjugation) had a much lower proportion of direct-reacting pigment. The homogeneity of the postmicrosomal jaundice group with regard to bilirubinemia was not explainable, but it is clinically useful for the diagnosis of cases with mixed jaundice pathology.

11734 DIRECT SERUM BILIRUBIN AND THE
SULFOBROMOPHTHALEIN TEST IN OCCULT

LIVER DISEASE. (E.) Gambino, S. R. (Englewood Hosp., N. J.), A. Other and W. Burns. J.A.M.A. 201(13):1047-1049, 1967.

Direct serum bilirubin and BSP retention were studied in various patients with liver disease to determine if there is a correlation between them, since bilirubin and BSP are cleared through the same hepatic pathway. Direct bilirubin levels and BSP retention were simultaneously measured in 52 patients with normal total bilirubin levels (less than 1.0 mg/100 ml); when direct bilirubin exceeded 0.20 mg/100 ml (21 patients), BSP retention was always abnormal; however, in 13 patients BSP was greater than 5% even though direct bilirubin was less than 0.20 mg/100 ml. Direct serum bilirubin was measured just before, and 45 min. after, BSP inj. in 22 patients with normal total bilirubin levels; in every case but 1, direct bilirubin increased after BSP inj. if BSP retention was greater than 4.5%. Serial measurements of direct bilirubin and total bilirubin were made in 13 patients recovering from known liver or biliary tract disease; in each case total bilirubin levels returned to normal before direct bilirubin levels. The authors failed to find any normal subject with a direct bilirubin level greater than 0.20 mg/100 ml. A positive correlation was found between BSP retention and increase in direct bilirubin levels that followed BSP inj., and these results support the clinical and chemical validity of direct bilirubin measurements as an index of occult liver disease.

11735 RENAL BILIRUBIN CLEARANCE IN LIVER PATIENTS. (E.) Fevery, J. (St. Rafael Acad. Hosp., Louvain, Belgium), K. Heirwegh and J. De Groote. Clin. Chim. Acta 17(1):63-71, 1967.

In human subjects, usefulness of renal clearance studies of bilirubin is limited by the chemical instability of this material and by important errors affecting short-time collections. In 0.25 mM disodium ethylenediaminetetraacetic acid at 4° in the dark, urinary bilirubin pigments are stable for 4 hr.; by calculating the clearance, using data obtained from successive short-time collections (chemical stability), these errors can be largely eliminated. Employing these principles, renal bilirubin clearances (35) were determined in 27 patients with various liver diseases: parenchymatous jaundice--viral hepatitis, 5; and cirrhosis, 5; obstructive jaundice--extrahepatic, 7 (nonmalignant in 4, and malignant in 3); intrahepatic, 4; cirrhosis with obstructive jaundice, 5; and unexplained cholestasis, 1. The effect of dehydrocholic acid was determined in 2 cirrhotic patients. Mean values of the 8-hr. clearances obtained by this method differed significantly in hepatitis, cirrhosis and obstructive jaundice. The 8-hr. clearances for those with hepatitis or cirrhosis were independent of the rate of urine output and of the serum bilirubin conc.; the difference between the mean of total bilirubi clearance found for both groups was highly significant (0.086 ± 0.020 for hepatitis, and 0.138 ± 0.014 for cirrhosis), and could have some diagnostic value in the differentiation of the 2 types of disease. The difference was even more striking between parenchymatous and cholestatic hepatitis. The mean value of the 8-hr. clearance of total bilirubin found in obstructive jaundice group (intra- and extrahepatic) differed significantly from the results obtained for patients with hepatitis or cirrhosis (0.334 ± 0.106 against 0.110 ± 0.033). Clearance values increased upon i.v. inj. of 2 g dehydrocholic acid. Values of renal clearance in obstructive jaundice correlated positively with serum bilirubin values, and evidence is presented to relate this effect to increased bile salt conc. in the blood of patients with obstructive jaundice. These observations are compatible with glomerular filtration as the main mechanism of renal elimination of bilirubin in man.

11736 LAPAROTOMY FOR JAUNDICE. (E.) Bourke J. B. (London Hosp., England), P. Cannon and H. D. Ritchie. Lancet 2 (7515):521-523, 1967.

Over a 4-yr. period, 152 patients underwent laparotomy due to jaundice; the actual diagnosis in these patients was carcinoma causing obstructive jaundice in 76, choledocholithiasis causing obstructive jaundice in 61, chronic pancreatitis and mass in head of pancreas in 3 each, sclerosing cholangitis, hydatid disease of the liver and hepatitis in 2 each, and pancreatic cyst, primary biliary cirrhosis, and drug jaundice (chlorpromazine) in 1 each. The jaundice was medical in 3 cases (2 with hepatitis, 1.3% of the cases; and 1 (0.7%) with drug jaundice). There was no mortality. The steroid diagnostic test, percutaneous liver biopsy and percutaneous transhepatic cholangiography produced misleadin or unhelpful results in some cases, and serious complications in others. Preoperative liver biopsies done on 13 occasions gave no help in establishing the diagnosis in 6, disclosed the features of extrahepatic obstructive jaundi in 4, of secondary carcinoma in 2 and the resul was misleading in 1 patient. Severe complicati from this procedure occurred in 2 patients: 1 required laparotomy due to biliary peritonitis and the other had to have blood-transfusion for i.p. hemorrhage. Percutaneous transhepatic cholangiography was done on only 3 individuals; in 2 it was unsuccessful because the bile ducts were not entered, and the third patient was successfully shown to have an obstruction in the choledochus, but still required surgery. It is suggested that if the cause of jaundice is in doubt, observation of the patient should continue for not less than 3 wk., by which time the diagnosis will often have become apparent. If a diagnosis has not been made after 6 wk. of jaundice, laparotomy should then be carried out

1737 A SYSTEM OF LABORATORY TESTS FOR THE DIFFERENTIAL DIAGNOSIS OF JAUNDICE. Pol.), Gorzkowski, E. (2nd Clin. Intern. Dis., zczecin, Poland), H. Szymańska, A. Nieczajew nd H. Myśliwicz-Rychlik. Pol. Arch. Med. Wewnet. 3(1):25-32, 1967.

ne results of the following laboratory determin- tions from 75 patients with viral hepatitis, 5 with cholelithiasis and 34 with jaundice f neoplastic origin were compared and analyzed or their diagnostic value: SGPT, SGOT, ldolase, phosphohexoisomerase, alkaline phos- hatase, Fe: Cu ratio, free and esterified holesterol, seromucoid and Jirgl's test. The xtreme values obtained in weekly intervals for iral hepatitis and mechanically-caused jaundice ere presented and the percentage of character- stic results determined. The arithmetic eans of the test values for the entire duration f jaundice were graphically compared. A test ystem is suggested which would facilitate the agnosis in the early as well as late phase of aundice and make it possible to follow the ynamics of the inflammatory process, functional ondition of the liver and patency of the liary tract. The tests recommended in the arly stage (7-10 days) of jaundice are: primary SGPT, esterified cholesterol/free cholesterol kaline phosphatase, Jirgl's test; secondary seromucoid, Fe/Cu. In the late stage of aundice (10 days or longer) the recommended ests were: primary - Fe/Cu, esterified choles- erol/free cholesterol, alkaline phosphatase, rgl's test; secondary - SGPT, seromucoid. aundice with significantly increased phospho- exoisomerase and alkaline phosphatase activity, high level of seromucoid, a strongly positive rgl test (+++) but with normal or only very ightly elevated transaminase activity and ecreased Fe level suggest a neoplastic origin this disease.

1738 PLASMA LIPIDS IN RECURRENT JAUNDICE OF PREGNANCY. (E.) Svanborg, (U. Goteborg, Sweden) and O. Vikrot. cta Med. Scand. 181(1):83-87, 1967.

ne levels of various plasma lipids were analyzed 8 patients (23-30 yr. old) with recurrent aundice of pregnancy during and after the aundice phase, and the data was compared with at from a previous study on 23 normal pregnant emales. Lysolecithin was slightly lower and riglycerides were slightly higher than in ormal pregnants. Free fatty acids were very nevenly distributed and showed no tendency oward either low or high values. Analysis blood samples 4 or more wk. after delivery owed levels which were essentially in agreement th those of healthy young nonpregnant females. is study showed that there was no difference plasma lipids between women with recurrent aundice of pregnancy and normal pregnants. ne results do not support the hypothesis that ne metabolic disturbances in this disease rovoke alterations in the plasma lipid level.

11739 THE SERUM FLOCCULATION TEST FOR THE DIFFERENTIAL DIAGNOSIS OF OBSTRUCTIVE JAUNDICE. SUMMING UP OF RESULTS AND EXPERIENCE. (E.) Jirgl, V. (Inst. Hemat. & Blood Trans., Prague). T. Gastroent. 10(2): 160-174, 1967.

In the serum flocculation test, 1.6 ml of blood serum and 4 ml of 0.1 N KOH are mixed, and 45 min. later 4 ml of 20% sulfosalicylic acid is added; 10 min. after mixing, the content is filtered; 5 ml of filtrate and 1 ml of 5% tungsten phosphoric acid in 2 N NaOH are mixed for 10 min. and then centrifuged for 15 min. at 1500 rpm. The supernatant is discarded and the residual precipitate dissolved in 6.5 ml of 10% Na_2CO_3 and 0.5 ml Folin-Ciocalteau phenol reagent, diluted in the ratio of 1:3 with water. After strong mixture by shaking, the result is determined against a dark background using strong incident light; results are characterized as 1) negative (tube contents remain clear or slightly bluish in color; 2) positive (+), opalescence; 3) positive (++), turbidity; and 4) positive (+++), precipitate. Results of a survey of the world-wide use of this test, based on more than 80 papers published on its use, showed that the av. values of correct results of the test were 91.15% and 89.55% for obstructive and hepatocellular jaundice, resp. The component which renders this test positive was found to have some properties in common with β-lipoprotein.

11740 THE SYNTHESIS OF TAUROCHOLIC AND GLYCOCHOLIC ACIDS IN HUMAN LIVER HOMOGENATES AND SUBCELLULAR FRACTIONS IN OBSTRUCTIVE JAUNDICE. (E.) Scherstén, T. (Sahlgrenska Hosp., Goteborg, Sweden). Scand. J. Gastroent. 2(1):49-58, 1967.

The synthesis of taurocholic and glycocholic acids was studied in the whole homogenate and in subcellular fractions of livers from 18 patients (10 men, 8 women; 26-86 yr. old; 4 with carcinoma of the pancreas and 14 with choledocholithiasis) operated on for cholestasis and compared with a control material (taken from 38 patients operated on for uncomplicated gastric or duodenal ulcer or nonobstructive gallbladder disease; this included 12 men and 26 women; 24-70 yr. old), with clinically normal liver function. A considerable decrease of synthesis of cholic acid conjugates was found in icteric homogenates, while no significant alteration of the synthesis was found in subcellular fractions containing the bile acid activating and transferring enzyme. The synthesis of cholic acid conjugates in icteric homogenates showed an inverse significant correlation to serum bilirubin values. Cholic acid conjugates added *in vitro* inhibited synthesis of conjugates in homogenates in homogenates and subcellular fractions. Bilirubin, added *in vitro*, brought about a significant decrease in synthesis of conjugates in homogenates but no changes of synthesis in the subcellular fractions mentioned. Soluble fraction as well as isolated mitochondria obtained from icteric human liver inhibited synthesis of conjugates in the microsome fraction and in the combined microsome fraction and L-fraction. Oligomycin significantly increased the synthesis of conjugates in icteric homogenates; it did not influence synthesis in the mentioned subcellular fractions from icteric levers or in homogenates from livers with clinically normal function. However, in no case did moligomycin raise the synthesis of bile acid conjugates in icteric homogenate to that of controls. It is suggested that the bile acid conjugating enzyme system is intact in cases of cholestasis of short duration (less than 14 days) and that the decreased synthesis of conjugates in icteric homogenates might be the result of a product inhibition of the conjugation reaction by retained bile acid conjugates and of stimulated mitochondrial ATPase activity caused by retention of bile components.

11741 CARDIAC OUTPUT AFTER PORTACAVAL SHUNT.

(E.) Johnson, G., Jr. (U. North Carolina Sch. Med., Chapel Hill) and J. Lambert. Ann. Surg. 166(2):207-212, 1967.

The following change in cardiac output was seen in 6 dogs after portacaval shunt: an elevation in the cardiac output in each dog with a mean increase for the series of 53 ml/kg/min. and cardiac output (unrelated to the wt. of the animal) increased by a mean of 645 ml/min. compared to 108 ml/min. (the mean cardiac output increase in 6 dogs who underwent sham operation). The mean difference for the series before and after sham operation was 1 ml/kg/min. Mean arterial pressure fell after both sham operation and after protacaval shunt; however, the drop was only significant in the group with the portacaval shunt. In both groups, pulse rate and right atrial pressure changes were inconstant. Cardiac output was the only independently-measured variable that demonstrated a significant change by the multivariant analysis technic. It is proposed that this increase is due to a decrease in peripheral resistance and an increase in venous return; alterations similar to those that accompany a systemic arteriovenous fistula. It is concluded that such an operation would be especially sound in patients with hyperdynamic cardiovascular systems.

11742 DIFFERENTIAL GLUCOSE TOLERANCE: A METHOD FOR DETERMINING PORTACAVAL SHUNT PATENCY.

(E.) Khanna, S. K. (Inst. Postgrad. Med. Educ. & Res., Chandigarh, India), V. K. Saini and T. Das. Canad. J. Surg. 10(3): 325-332, 1967.

An evaluation of the usefulness of conducting differential glucose tolerance tests is reported, in which the glucose level of blood samples from the inferior vena cava were compared with those taken from a peripheral vein, for the purpose of assessing portacaval shunt patency in both dogs and man. After determining fasting glucose levels in both the inferior vena cava and peripheral blood, 50 g of glucose was admin. to 10 mongrel dogs by way of gastric tube and then the glucose values were obtained from these same sites at 20-min. intervals for 2 hr. The same dogs were then subjected to side-to-side portacaval shunt. Differential glucose tests were conducted on the second postoperative day and the dogs were then sacrificed to determine shunt patency. At peak glucose absorption, the max. I-P difference (difference in glucose conc. between the inferior vena cava and a peripheral vein) for control dogs was 6 ± 0.5 mg/% as compared to a value of 38 ± 1.7 mg/% in the same dogs but now with Eck fistulae. Clinically, 5 untreated patients with portal hypertension showed a max. I-P value in the fasting state of 2 ± 0.7 mg/% as compared to a max. I-P value during peak glucose absorption of 10 ± 0.8 mg %. In 5 patients with previously performed portacaval shunt (4 wk. to 1.5 yr. age) differential glucose tolerance was conducted. The max. I-P value during fasting was 3 ± 0.9 mg % as compared with a value of 32 ± 2.7 mg % during peak glucose absorption. This method is recommended as an easy, reliable routine test for determination of the portacaval shunt patency in man.

11743 SELECTIVE TRANS-SPLENIC DECOMPRESSION OF GASTROESOPHAGEAL VARICES BY DISTAL SPLENORENAL SHUNT.

(E.) Warren, W. D. (U. Miami Sch. Med., Fla.), R. Zeppa and J. J. Fomon. Ann Surg. 166(3):437-455, 1967.

Critical analysis of routine portacaval shunt therapy for esophageal varices reveals a lack of success in increasing survival; control of bleeding varices is excellent, but an increased death rate from hepatic complications has negated this achievement. Nonshunting surgical procedures are superior in hepatic protection, but are accompanied by a high incidence of recurrent bleeding. A new operativ procedure is described in which gastrosplenic isolation, gastric devascularization and selective venous shunting is accomplished by an *in situ* spleen and a distal splenorenal shunt (end-to-side anastomosis of the splenic vein to the left renal vein); the rationale of this procedure is to decompress the area critical for control of hemorrhage while maintaining a high pressure intestinal venous system and preserving portal flow to the liver. This operation was performed on 6 patients (3 of each sex; 40-69 yr. old) with bleeding esophageal varices; in 4 a distal splenorenal shunt with gastrosplenic isolation was done, while in 2 the stomach was devascularized but the spleen was left in place; 2 of the

tients subsequently died, but the shunt was
tent in each. Successful accomplishment of
e above-mentioned goal was demonstrated
diographically, with diversion of splenic
ow through a distal splenorenal shunt, while
perior mesenteric flow continued to perfuse the
ver; the proposed metabolic advantage was
nfirmed by a markedly superior response to
otein tolerance testing. From these
eliminary studies it is suggested that use of
s type of procedure is indicated in patients
th high vol. portal flow to the liver; typical
amples are seen in early cirrhosis with
rked splenomegaly and in so-called idiopathic
rtal hypertension.

744 CALCIFICATION IN THE LIVER AND PORTAL
SYSTEM. (E.) Haddow, R. A. (St.
rtholomew's Hosp., London) and R. A. Kemp-Harper.
n. Radiol. 18(3):225-236, 1967.

ree patients are described with portal vein
cification; this was associated with cirrhosis
1 patient and portal hypertension due to
rombosis of the portal vein in the others.
addition, 3 patients with calcification in
e liver are described; in 1 patient this was
e to a primary carcinoma of the liver, in
e second to a bile duct carcinoma and in
e third, calcification occurred in a gumma.
e differential diagnosis of hepatic calcifica-
on is discussed in detail, including calcifica-
on in a hydatid cyst, liver metastases,
mary liver tumors, hepatic artery aneurysms,
er abscess, tuberculous or histoplasmosis
dules, brucellosis granulomata, gumma and
atic stones. The significance of finding
cification in a cirrhotic liver is emphasized,
ce this is strong presumptive evidence of the
elopment of a malignancy.

745 LOCALIZED "RADIATION HEPATITIS" AS
DEMONSTRATED BY SCINTILLATION SCANNING.
) Concannon, J. P. (Allegheny Gen. Hosp.,
tsburgh, Pa.), A. Edelmann, J. C. Frich, Jr.
G. Kunkel. Radiology 89(1):136-139, 1967.

ourse of radiotherapy for malignant neoplasm
patients with malignancy of the testis and
omen with Stage II Hodgkin's disease) was
lowed by inj. of radioactive colloidal Au
subsequent liver scinti-scanning. Three
treatment liver scans in 3 patients were
mal, while definite defects were observed in
post-treatment scans obtained from all 6
ients. These defects were characterized by
uced radioactivity in those areas where
radiation portals crossed the liver.
iotherapy levels ranged from 4000-5000 rads
no symptoms of "radiation" hepatitis were
ed. There were no uniform changes evident
liver function and the role of chemotherapeutic
nts in the possible etiology of "radiation"
atitis was excluded since 3 of the patients
e given only radiotherapy. It is thought that these defects may represent either the direct radiation effects on the function of Kupffer cells or perhaps radiation effects on the liver parenchyma which might prevent the movement of colloidal Au particles to the Kupffer cells.

11746 DETERMINATION OF INDOCYANINE GREEN CLEARANCE BY DICHROMATIC EAR DENSITOMETRY AS A MEASURE OF LIVER FUNCTION. (Ger.) Paumgartner, G. (U. Clin. Vienna), J. Longueville and C. M. Leevy. Wien. Z. Inn. Med. 48(6):227-235, 1967.

Indocyanine green clearance has been used as a test of liver function in the same way as BSP clearance; this nontoxic dye is excreted from the liver in the same manner, and has an absorption spectrum at 800 mμ which permits the continuous measurement and recording of its blood conc. by an ear densimeter. This method was tested on 10 healthy subjects between the ages of 20 and 60 yr. with normal liver histology, and on 44 patients in the same age group with diagnoses of hepatopathologies secured by biopsy (12 cases of viral hepatitis, 12 of fatty liver, and 20 of liver cirrhosis). A dichromatic ear densimeter was used; the instrument was calibrated against a spectrophotometrically-measured conc. of the dye. During the test, blood samples were obtained from indwelling cannulae; the dye conc. in the plasma was established by spectrophotometry. The clearances obtained by the 2 methods (densimetry and direct measurement of dye conc. in plasma) were identical. Two conc. of dye were used; 0.5 mg/kg and 5 mg/kg; clearance measurements were equally precise with the 2 conc. Clearances accurately reflected the degree of liver damage as assessed by study of biopsies. The sensitivity of the method depends upon the conc. of dye used; mild abnormalities of hepatic function require a higher conc. (e.g., 5 mg/kg) whereas in severe liver disease 0.5 mg/kg is sufficient.

11747 COMPARATIVE INVESTIGATION ON THE HEPATIC BLOOD SUPPLY IN DOGS WITH THE INDOCYANINE GREEN METHOD AND THE HENSEL HEAT-CONDUCTING PROBE WITH LIGATURE OF THE HEPATIC ARTERY. (Ger.) Bär, U. (U. Clin. Gottingen, Germany), J. Boettcher, U. Fiedler, H. E. Hoffmeister and C. E. Zöckler. Z. Gastroent. 5(4):222-227, 1967.

Liver blood flow was measured by the indocyanine green method and the Hensel heat transducing probe in 9 dogs (14-16 kg) before and after complete ligation of the hepatic artery. Blood flow in the left lobe of the liver was also determined by these methods. The vascular system of the liver tissue was examined histologically. The blood supply to the liver determined by the dye method in 9 anesthetized dogs av. 21.9 ml/kg/min. or 437 ml/min. prior to ligation. A decrease in blood flow occurred immediately after ligation followed by a compensatory rise. With the dye method the range of the increased blood flow was so great that it was statistically insignificant. The Hensel probe showed an av. fall in 9 animals of 35% in blood flow 2 min. after ligation of the artery with a compensatory rise of about 15% 6.8 min. after ligation; this compensatory rise (presumably due to increased relative portal vein blood pressure) tended to establish a new level of blood vol. flow. The same sequence was found for the left lobe as for the whole liver. No correlation was established between changes in blood flow and the histologic cross-sectional areas of blood vessels.

11748 CLINICAL EXPERIENCES WITH SULFOBROMOPHTHALEIN IN LIVER DIAGNOSIS. (Ger.) Lemke, E. (Reg. Hosp., Potsdam, Germany). Z. Aerztl. Fortbild. (Jena) 61(16):813-816, 1967.

The BSP test was admin. to 750 patients with liver damage of different etiologies. The activity of SGOT and SGPT, serum Fe level, the sedimentation rate, and the thymol precipitation test were also given to these patients for comparison and evaluation of the BSP test. Electrophoresis of serum proteins was also done for the entire group. Among 134 with persistent hepatitis, among 142 recently recovered from acute hepatitis, in 61 with chronic hepatitis and 77 with decompensated liver cirrhosis the BSP test indicated a pathological condition in all cases. In 94 cases of compensated liver cirrhosis the test showed pathology in 92.5% and a normal state in 7.5%. Among 65 with fatty livers the corresponding percentages were 90.7 and 9.3. A pathological condition was discovered by the test in 94.3% of 83 individuals with cardiac insufficiency and decompensated hypertension, but in only 70% of 53 with acute cholangitis and in only 26.8% of 41 with liver metastases. None of the other tests employed were nearly as accurate. Numerical values were not given for the other tests. A chart of these tests in terms of positive, negative, normal, elevated, and other values is presented.

11749 INFLUENCE OF SINGLE CHOLERETICS UPON THE COURSE OF THE SULFOBROMOPHTHALEIN EXCRETION CURVE RECORDED IN VIVO. (Dut.) Versieck, J. (Acad. Hosp., Gent, Belgium), J. Verbeke and F. Barbier. T. Gastroent. 10(1): 41-55, 1967.

The excretion of BSP with and without an admin. choleretic in the bloodstream was recorded by an automatic analyser in the heparinized blood (10,000 U) of patients inj. i.v. with 5 mg/kg of BSP. Test curves without admin. choleretics showed excellent reproducibility in 12 patients with a wide diversity of pathologies such as cholelithiasis, hypertension, diabetes, neuroses, colitis, fatty liver, liver cirrhosis, chronic hepatitis, and others. The choleretics and dosages used were Na-dehydrocholate (1.5-4.0 g), 7-morpholino-ethyl-8-benzyltheophylline (1 g), Na cyclobutyrate (2-4 g), and phenyldimethylaceti acid (2-4 g). The results were not uniform. Where Na dehydrocholate markedly prolonged BSP clearance from the plasma, phenyldimethylacetic acid did not produce any change; 7-morpholinoethyl-8-benzyl theophylline prolonged plasma excretion of the dye only during the second part of the curve; and Na cyclobutyrate produced results showing acceleration, no change, or delay in the removal of BSP from the plasma.

11750 A COMPARATIVE EVALUATION ASSAY OF THE LIVER DAMAGE IN THE COURSE OF TOXEMIA OF PREGNANCY AND IN THE VIRAL INFECTIOUS HEPATIT IN PREGNANCY. (Pol.) Herbst, J., B. Nowakowska and J. Wencel. Ginek. Pol. 37(12):1309-1312, 19

Thymol tests, serum transaminase activity, serum uric acid levels, serum bilirubin levels and urinary urobilinogen determinations were made on 51 women with late toxemia of pregnancy and results compared with those obtained from 37 pregnant women with viral hepatitis. Serum transaminase activity was only slightly elevated in late toxemia of pregnancy in contrast to high activity among pregnant women with viral hepatit Thymol test values were also slightly elevated, but were lower than in viral hepatitis. Serum uric acid levels were significantly elevated in toxemia of pregnancy with a mean value of 6.6 mg while in viral hepatitis the levels were within normal limits (3.6 mg%). Urinary urobilinogen w elevated in 33% of patients with toxemia of preg nancy indicating changes in the liver. It is co cluded that even in the absence of clinical symp toms (jaundice) liver function disturbances occu in many cases of late toxemia of pregnancy and c be demonstrated by laboratory tests.

11751 IMMUNOCHEMICAL DIAGNOSIS OF PRIMARY CANCER OF THE LIVER. (Rus.) Assekritova, I. V. (Inst. Exp. Clin. Oncol., Moscow), G. I. Abelev, N. A. Kraevskii, S. D. Perova and N. I. Perevodchikova. Vestn. Akad. Med. Nauk SSSR 22(5):75-81, 1967.

Parenchymal liver cells of rat or mouse embryos and those of up to 3-wk.-old animals are capabl of synthesizing α_f-globulin, a serum component not found in the sera of the adult, healthy animals. Hepatoma cells are able to synthesize this protein in the adult animals and to releas it into the serum. The α_f-globulin content of serum samples collected from 70 patients with hepatic tumors was determined by precipitation in agar-gel and immunoelectrophoresis. Sera against human α_f-globulin were prepared by repea inj. into rabbits of serum collected either fro human embryos or from newborn children. The antisera were absorbed by normal human sera. T α-globulin fraction of human embryo serum serve as an antigen in the reactions. Of the 70 patients 18 had primary cancer of the liver, 2 be nign hepatic tumors, and 50 metastatic hepatic tumors. The control groups consisted of 58 atients with various hepatic tumors, and of 60 atients with hepatic diseases other than tumor. era of 10 of the 18 patients with primary cancer f the liver were positive for α_f-globulin. This lobulin was found mostly in the sera of patients ith hepatocellular structure of primary liver ancer (7 of 8). Sera of 4 of 23 patients with eratoblastoma of the testis, containing elements f embryonic cancer or of seminoma and chorio- pithelioma, were also positive for α_f-globulin. ne explanation of this finding remains obscure. era of patients from other groups were all nega- ive for α_f-globulin.

1752 THE ACTION OF THE CYTOSTATIC METHOTREXATE ON THE WATER CONTENT AND DRY EIGHT OF NUCLEUS AND CYTOPLASM OF REGENERATING IVER CELLS IN THE RAT AFTER PARTIAL HEPATECTOMY. Ger.) Schiemer, H. G. (Goethe U., Frankfurt/M., ermany), G. Günther and D. Sina. Frankfurt. Z. ath. 76(4):427-434, 1967.

f 8 rats (132-258 g) where the ventral lobe f the liver was excised, 5 were inj. i.p. with .5 ml of 2% methotrexate soln. 24 hr. after artial hepatectomy. All animals were killed 48 r. after operation and liver tissue from each was ixed; some fresh liver tissue was prepared as luid mounts in Tyrode-0.5% gelatin soln. for tudy under the interference microscope. The iddle optical sections of the nucleus and of the ytoplasm of cells were measured from planimetric rawings made under monochromatic light. Similar easurements were made of the fixed (e.g., dehy- rated) liver cells. Using formulae derived by ne author, the wet vol. (in μ^3) and the dry wt. 10^{-12} g) of cells, nuclei and cytoplasm were alculated. In normal regeneration a considerable ncrease occurred in vol. of nucleus from 409 to 76 and of cytoplasm from 6780 to 8340; in regen- ration with methotrexate the nuclear vol. in- reased to 474 and the cytoplasmic vol. to 8230. ry wt. rose from 57.5 to 63.9 (normal regenerat- ng nucleus) and from 563 to 689 (normal re- enerating cytoplasm). Dry wt. in regeneration ith methotrexate went to 58.9 (nucleus) and 626 cytoplasm). Vol. increases under the influence f methotrexate (both nuclear and cytoplasmic) ere similar to those in normally regenerating ells. The increase in dry wt. of the cytoplasm nd, especially, of the nucleus (less than 25% of he normal) was sharply curtailed by methotrexate, ndicating a reduction of synthesis. All the alues are statistically significant.

11753 CIRRHOSIS AND PRIMARY CANCER OF THE LIVER. COMPARATIVE STUDY IN TOKYO AND INCINNATI. (E.) Mori, W. (Tokyo Med. Dent. oll.). Cancer 20(5):627-631, 1967.

f 3232 autopsies reviewed in Tokyo, an overall ncidence of 59 cases (1.8%) of primary hepatic ancer and 124 cases (23.4%) of liver cirrhosis as revealed. These cases of primary liver cancer nvolved 29 patients with and 30 patients without liver cirrhosis with 42 of the tumors being of hepatocellular origin (37 in males and 5 in females), while 15 were determined to be of cholangiocellular origin. The remaining 2 cases consisted of 1 case of hepatoblastoma and 1 case of hepatic mixed tumor. These findings were comparable to those reports from Asian-African areas. Compared to findings collected in Cincinnati by E. A. Gall, both studies reflected the fact that nonspecific cirrhosis (either postnecrotic or posthepatitic) was the predominant complication of hepatocellular carcinoma. Nutritional and other specific cirrhosis showed no significant concomitant association with hepatocellular carcinoma. The association of cholangiocellular carcinoma and cirrhosis was absent in the Tokyo study, but was as high as 45% in the Cincinnati study. Postnecrotic and posthepatitic cirrhosis (hepatoma-related) are more prevalent in Tokyo and this may account for the higher incidence of primary hepatic cancer in that city. Nutritional cirrhosis (hepatoma-unrelated) was found to be more prevalent in Cincinnati. Congenital atresia was responsible for 17 of 25 cases of biliary cirrhosis in infants autopsied in Tokyo.

11754 GLYCOGEN STORAGE DISEASE IN ISRAEL. A CLINICAL, BIOCHEMICAL AND GENETIC STUDY. (E.) Levin, S. (Kaplan Hosp., Rehovoth, Israel), S. W. Moses, R. Chayoth, N. Jagoda and K. Steinitz. Israel J. Med. Sci. 3(3):397-410, 1967.

Over the last 13 yr. in Israel, 49 cases of glycogen storage disease have been diagnosed, of whom 26 have been typed as to their specific enzyme deficiency. All of the latter were in the non-Ashkenazi Jewish community (of North African origin) and 73% had a deficiency of amylo-1,6-glucosidase (debrancher enzyme). This figure is to be compared with 56% from Holland, 25% from Belgium, 21% for U.S.A. and 8% from Sweden. In Israel, the incidence among Jews of European background was about the same as that reported for Sweden. In 7 cases of the amylo-1,6-glucosidase deficiency, reduction in glucose-6-phosphatase activity was also evident. It is suggested that this reduced activity is secondary to a regulatory gene abnormality which brought about the deficiency in the debranching enzyme and not due to a second structural gene defect. All efforts to discover a common ancestry or interrelationship between the 11 families involved was unsuccessful but in 9 the parents were blood relations. The data suggested an autosomal recessive made of inheritance. The glycogen content of liver (range of 4.9-17.1 g/100 g wet tissue) and muscle (ranged between 2.8-11.0 g/100 g) was abnormally high in all cases examined. Fasting hypoglycemia was present in 19 of 22 and hyperlipidemia in 9 of 13 tested. A diabetic-like curve was obtained in all of 14 given the glucose tolerance test and elevation of blood glucose was seen in all of 16 given the galactose tolerance test. Symptomatic hypoglycemic attacks were reported in 14 cases, but generally the attacks were mild.

11755 HARTNUP DISEASE. (E.) Oyanagi, K. (Aomori Prefect. Cent. Hosp., Japan), M. Takagi, M. Kitabatake and T. Nakao. Tohoku J. Exp. Med. 91(4):383-395, 1967.

The first cases of Hartnup disease in Japan (2 typical cases and 6 proposed carriers through 3 generations) are reported. The first patient evaluated, a 19-yr.-old girl, manifested typical bilateral dermatitis similar to pellagra on her extremities and face and, also, a 20-day history of ataxic gait. Paper chromatographic studies of her urinary amino acid and indole excretion was abnormal with levels of free amino N_2 being 1000 mg/day and also marked spots of indican, tryptophan, indoleacetic acid, indoleacetylglutamine and indoleacrylglycine being noted. Marked improvement was observed, with loss of dermatitis and ataxic gait, after 6 mo. therapy with nicotinamide. The second patient evaluated, a 21-yr.-old boy, also showed characteristic symptoms of Hartnup's disease. This second patient, however, recovered from his ataxic gait without nicotinamide therapy. Paper chromatographic studies and tryptophan-loading tests were conducted on urine samples taken from these 2 patients' parents, siblings, maternal first cousins, and maternal and paternal grandmothers and grandfathers. Indicanuria and increased excretion of tryptophan and indoleacetic acid were noted in 2 siblings, 2 maternal first cousins and both grandfathers. However, no external signs of Hartnup;s disease were observable. It is suggested that these latter patients may represent carriers of this disease.

11756 REPLANTATION OF THE LIVER IN DOGS. (E.) Alican, F. (U. Mississippi Med. Ctr., Jackson) and J. D. Hardy. J. Surg. Res. 7(8): 368-375, 1967.

Liver replantation was performed in 60 dogs in an attempt to examine the effects of orthotopic autotransplantation as a prelude to the investigation of the immunological factors involved in orthotopic homotransplantation. Thirty-seven dogs survived longer than 3 days, and 15 longer than 1 mo. At the time of report, 3 dogs still survive at approx. 18 mo., and 1 delivered a litter of 12 puppies. Certain useful modifications of previously-described liver transplantation technics were noted. The excised liver was perfused with cold soln. without delay, but total body hypothermia was avoided. During replacement of the liver, the portal and caval blood was returned to the heart by means of a single external bypass from the caudal end of the divided portal vein to the external jugular vein; after the portal vein and infrahepatic vena cava had been temporarily joined by an autogenous vein graft. The arterial supply was restored by end-to-end anastomosis of the common hepatic artery. The incidence of vascular thrombosis was strikingly low. Serum bilirubin levels remained normal in most animals. Blood glucose levels frequently declined during the first postoperative day, but then usually remained normal. The SGOT level rose immediately in most animals, but usually declined to normal after 2 wk. in chronic survivors. Albumin decreased and globulin increased in long-term survivors. The serum alkaline phosphatase level rose within 48 hr. after operation and usually declined in several days, but in some cas it remained elevated for several mo. Development of hepatic venous outflow block, abnormal bleedin or subsequent ascites was rarely encountered when the organ was well-preserved with cold soln. and trauma avoided by gentle handling. In contrast, when cold preservation was inferior or traumatic manipulation did occur, not only these complications but subsequent liver abscesses due to focal necrosis were noted. The patency of the vascular anastomoses was good in most animals; thrombosis of the hepatic artery occurred in only 5 animals, portal vein thrombosis occurred in 2 and vena caval thrombosis in 3. It is suggested that thes results provide a description which was formerly lacking of the course of longterm survivors of canine liver replantation.

11757 COMPARISON OF SOME INDICES RESULTING FROM EXTRACORPOREAL PERFUSION WITH THE USE OF HOMO- AND HETEROLOGOUS LIVER. (Pol.) Alichniewicz, A. (3rd Surg. Clin., Lodz, Poland), J. Martin, H. Zalech, A. Joss, A. Dziewałtowska, R. Markert and M. Borchardt. Pol. Przegl. Chir. 39(3):225-229, 1967.

Extracorporeal hepatic perfusion experiments were performed on 20 dogs using homologous and heterologous livers. Ten dogs had the livers of other dogs, 4 had pig's livers and in 6 had calf's livers. Pig's liver was unsuitable causing agglutination of RBC and death of the dogs within 10-20 min. Blood pH decreased 2.3% with homologo liver after 2 hr. of circulation and 1.2% with heterologous (calf's) liver after 4 hr. The hemolysis level av. 28 mg% with homologous but 59% with heterologous liver after 4 hr. O_2 uptake was 35.0% lower with heterologous than homologous circulation after 3 hr. Both homo- and heterologous livers excreted 4-6 ml of bile/h In BSP excretion tests dogs with heterologous liver completely excreted this substance 40 min. sooner than those with homologous liver (60 min. as compared to 100 min.). In NH_3-loading experiments the NH_3 returned to initial levels after 100 min. with homologous and after 70 min. with heterologous livers. Coagulation time increased from 8 min. at the beginning to 28 min. after 2 hr. Electrophoretic studies of plasma proteins showed a slight decrease of albumin but definite increase of the γ-globulin fraction. It is concluded that including homologous or heterologous (calf's) liver into the blood circulation of dogs maintains the principal physiologic function for several hr.

11758 ASSESSMENT OF LIVER FUNCTION IN MICE. (E.) Becker, B. A. (U. Iowa Coll. Med. Iowa City) and G. L. Plaa. Lab. Anim. Care 17(3) 267-272, 1967.

rochemical methods and their limits of normalcy the assessment of liver function in a colony Swiss Webster-type male mice are presented to those who wish to study liver function or evaluate liver function prior to chronic toxty studies or following exposure to disease. ng 3 separate groups of mice the plasma conc. the upper limit of normalcy for bilirubin, and SGPT was 0.1 ± 0.2 mg% and 1.0 mg%, ± 0.7 mg% and 3.1 mg%, and 28 ± 11 U and 61 U, p. No positive responses for urinary bilirubin e obtained in the urine from 30 untreated mice. n cannulation of bile ducts, flow began within 5 min. at the initial rate of 0.04-0.07 ml/hr. continued for some hr. (a few produced bile 48 hr.). This measurement was made by the . inj. of 0.01 ml/g of 0.2% soln. of fluoresn. The following scheme is presented for aining a sample group from a mice colony conting of 900 mice housed 10 in a cage: Take 1 se from each cage and place in a single conner and then after mixing the cages well, select domly 3 groups of 30. One group each is then lyzed for plasma bilirubin, SGPT and BSP levels if no animal in any group exceeds the resp. er limit of normalcy, all members in the origl population are considered to have normal er function.

59 RADIOISOTOPE SPLENOPORTOGRAPHY IN CLINICAL PRACTICE. PRELIMINARY RESULTS. .) Lenti, G. (U. Cagliari, Italy), A. Pelleni, G. Pagano, E. Massacci and M. V. Brotzu. weiz. Med. Wschr. 97(34):1117-1122, 1967.

11844 BETA-GLUCURONIDASE IN ACUTE CARBON TETRACHLORIDE DAMAGE TO THE RAT LIVER.

(Ger.) Nilius, R. (Martin Luther U., Halle-Wittenberg, Germany), F. W. Rath and A. Gomez. Z. Ges. Exp. Med. 144(2):157-172, 1967.

Activity of β-glucuronidase was determined in the serum and liver homogenates in white rats (200-250 g) inj. s.c. with 0.5% CCl_4/100 g body wt. in a 50% soln. of sunflower oil, in other rats inj. with oil only and in still other rats (non-inj.) as controls. Animals were killed at 2.5, 9, 24, 32, 48, 72, 96 and 192 hr. after admin. of CCl_4, and the blood and liver obtained. Some of the liver was used for biochemical determination of the enzyme and some for histologic and histochemical studies. After inj. of CCl_4 total β-glucuronidase activity in the liver was reduced to 50% reaching its minimum at the appearance of necrosis (32-48 hr.). With regeneration (after 48 hr.) of the liver cells, the enzyme activity increased in the homogenates. In all phases of CCl_4 admin. serum activity was higher (60-70% of total enzyme activity) than in normal rats (40%). The conc. of β-glucuronidase in the serum increased after inj. of CCl_4 up to 4-5 times normal. A characteristic diphasic enzyme elimination from the serum was noted. A loss of enzyme was observed histochemically in the liver before any structural changes were seen in the hepatic cells; with increasing visual cell damage, enzyme conc. declined. Necrotic cells showed no β-glucuronidase activity. With regeneration, enzyme conc. was restored to normal. These findings agree with the lysosome concept.

11845 CHANGES OF LIVER PARENCHYMAL CELLS FOLLOWING ADMINISTRATION OF ACTINOMYCIN C AND D.

(Ger.) David, H. (Humboldt U., Berlin) and I. Marx. Acta Biol. Med. German. 18(2): 259-273, 1967.

White mice were inj. i.p. or intrasplenically with 0.1-1.0 μg/g body wt. of actinomycin C or D, carcinostatic agents, 1, 2, or 3 times (at 0 hr., 24 hr., and 48 hr.). Liver was excised at different intervals from 45 min. to 72 hr. and prepared for ultramicroscopy. As early as 45 min. after the actinomycin dose, layering of karyoplasmic granules, flocculation with lightening of the background and clumping at the nuclear membrane and around the nucleolus occurred. Concurrent changes took place in the nucleoli: the nucleolonemata and the pars amorpha separated, both staining with osmium. Membrane-like layers surrounded the altered nucleoli separated by a clear area from the karyoplasm; all stages of disintegration of nucleoli were present. The nuclear membrane showed vesicular formation; the number of membrane pores remained normal and some nuclear inclusions were noted. After the second hr. following inj. changes became visible in the cytoplasm. The ribosomes not attached to the membranes were at some distance from them; all cytoplasmic regions had numerous polysomes as well as larger membrane complexes of the granular reticulum. Destruction of reticulum or ribosomes was never observed. The smooth endoplasmic reticulum became altered with small vesicles and with glycogen deposits which increased with increased number of actinomycin inj. After the second hr. the ground plasma became very clear so that the organelles seemed to float in empty space. In some cells the mitochondria were swollen, hyperplastic, lackin matrix substance, and with fragmented cristae. Ring-shaped mitochondria were noted. After 1 o more admin. of actinomycin, microbodies but not cytolysosomes increased in the liver cells. Lysosomes were present in the Golgi field. Osmiophilic granules collected in the space of Disse, the microvilli were decreased in number and swollen and fat globules became common. Th changes result from actinomycin-induced damage to RNA synthesis in turn reducing synthesis of cytoplasmic protein.

11846 VITAMIN E AND STRESS. 4. THE METABOLISM OF D-α-TOCOPHEROL DURING NUTRITIONAL HEPATIC NECROSIS IN THE RAT AND THE EFFECTS OF SELENIUM, METHIONINE AND UNSATURATED FATTY ACIDS.

(E.) Green, J. (Vitamins Ltd., Tadworth, Surrey, England), A. T. Diplock, J. Bunyan, I. R, Muthy and D. McHale. Brit. J. Nu 21(2):497-506, 1967.

Liver necrosis was induced in rats given diets deficient in Se and vitamin E and the metabolis of (^{14}C)D-α-tocopherol was studied during development of the disease. When a torula yeas diet (containing sufficient amount of yeast to provide essential fatty acids) was used, the addition of 5% cod-liver oil fatty acid methyl esters produced only a slight decrease in the time taken to produce the disease, compared to controls given methyl oleate; methionine had little protective effect. The metabolism of th radioactive tocopherol was unaffected by dietar lipid, methionine or Se, and was not influence by the development of necrosis. When a casein diet (devoid of fat and containing insufficient Se to prevent liver necrosis) was used, the addition of small amounts of linoleic acid to the diet (as 2% maize oil fatty acid methyl esters) decreased the time required to produce the disease and increased its incidence. However, metabolism of the radioactive tocopherol was independent of dietary lipid or Se. It is suggested that either Se or vitamin E may be necessary for effective utilization of the rat' requirement for linoleic acid.

11847 STUDIES ON THE INFLUENCE OF 7-[2-HYD
3(N-2-HYDROXYETHYL-N-METHYLAMINO)-PR
1,3-DIMETHYLXANTHINE-PYRIDINE-3-CARBOXYLATE (X
THINOL NICOTINATE) ON THE LIPID INFILTRATION I
THE RAT LIVER AFTER CHRONIC INTOXICATION BY CA

TRACHLORIDE AND ALCOHOL. (Ger.) Brenner, G.
. A. Wulfing Co., Dusseldorf, Germany).
zneimittelforschung 17(8):991-993, 1967.

ite rats in 6 groups were used in these studies;
) normal controls; (2) animals inj. s.c. with
x 770 mg CCl_4 in olive oil/kg/wk.; (3) rats
j. as in Group 2 with CCl_4 plus 500 xanthinol
cotinate/day in the drinking water; (4) animals
min. CCl_4 as in Group 2 for 2 and 5 wk.
llowed by 500 mg xanthinol nicotinate/kg/day
r 3 days in the drinking water plus 300 mg/kg/day
v.; (5) animals maintained on 15% ethanol in
ace of drinking water for 3 mo.; (6) rats
intained for 3 mo. on 15% ethanol followed by
tubation of 500 mg xanthinol nicotinate/kg,
ice/day for 3.5 days. The livers were extracted
r total lipids, and the amount of unsaturated
tty acids determined; in the animals receiv-
g alcohol the unesterified fatty acids of the
asma were also measured. Fatty degeneration of
e liver induced by CCl_4 was reduced by 55% by
e concomitant admin. of xanthinol nicotinate.
ter 5 wk. treatment with CCl_4 the lipid
filtration of the liver was decreased by 25%
the therapeutic admin. of xanthinol nicotinate.
tty degeneration of the liver resulting from
ronic intake of alcohol was reversed and the
ver lipid content reduced below normal values
ter 3 days treatment with xanthinol nicotinate.
e compound also decreased the free fatty acids
the blood plasma of rats after chronic alcohol
toxication.

48 BIOTIN DEFICIENCY AND OROTIC ACID FATTY LIVER IN THE RAT. (E.) Sarma,
S. R. (U. Pittsburgh Sch. Med., Pa.) and
Sidransky. J. Nutr. 92(3):374-376, 1967.

male Sprague-Dawley and Wistar rats were
vided into 2 groups: rats fed a basal diet
d rats fed a biotin-deficient diet, both
libitum for 10 wk. The basal diet was com-
sed of 20% vitamin-free casein, 11% autoclaved
g white, 5% corn oil; 4% salts, 5% vitamin-
crose mixture and 55% sucrose, and it also
ntained 20 μg biotin/100 g diet. The biotin-
ficient diet was identical with the basal diet,
cept that no biotin was added and 11% raw egg
ite (spray-dried) was used. After 10 wk., the
groups were further subidivided according to
e diet that was force-fed for 3 or 6 days.
imals fed the basal diet were divided into a
oup fed just the basal diet, and a group fed
e basal diet containing 1% orotic acid. Animals
d the biotin-deficient diet were divided into
group further fed the biotin-deficient diet
one, one fed this diet containing 1% orotic
id and another group fed the biotin-deficient
et containing 1% orotic acid and in addition,
0 μg DL-biotin s.c. during the first day of
rce-feeding. All animals force-fed the orotic
id-containing diets developed fatty livers.
ese results indicate that biotin deficiency of
self does not influence the development of
tty liver due to orotic acid. Dietary consumption must be considered as an influencing factor in the pathogenesis of nutritionally-induced or related fatty liver.

11849 6-AZAURACIL DERIVATIVE AS LIVER FUNCTION TEST IN THE COURSE OF CYCLOPHOSPHAMIDE TREATMENT. (E.) Timar, M. (Inst. Chem. Pharm. Res., Bucharest), I. Hädrich, E. Banu, I. Nitelea and M. Teodorescu. Farmaco [Prat.] 22(7):403-409, 1967.

A dose of 200 mg/kg of 5-mercapto-6-azauracil was admin. s.c. 9 days before and 1, 3 and 8 days after i.v. admin. of a single dose of 130 mg/kg cyclophosphamide to male Wistar rats, and the content of the drug and its metabolites in urine was assessed chromatographically. Parallel tests were performed with BSP, using a 0.1% soln. admin. i.v., 0.5 ml/100 g animal. The mechanism of 5-mercapto-6-azauracil metabolism was studied by assessing the effect of this substance (500 mg/kg for 3 days) on the duration of sleep produced by hexobarbital, 50 mg/kg, admin. i.v. The results indicated that repeated admin. of 5-mercapto-6-azauracil stimulates drug-metabolizing enzymes in the liver, this being shown by shortening of the duration of hexobarbital anesthesia and by modifications in the chromatogram of the metabolites in the urine; the latter, appearing as black spots, decreased after repeated admin. of 5-mercapto-6-azauracil, and there was a parallel increase in the number of blue spots, indicating accelerated elimination of the drug. In intoxication with cyclophosphamide, elimination of 5-mercapto-6-azauracil was maintained at a high rate, but the proportion of unaltered substances and its metabolites was different. Hence in the course of cyclophosphamide intoxication, elimination of 5-mercapto-6-azauracil maintained the same character as in controls, but its metabolism was modified. These metabolic differences due to liver function were not shown by the BSP clearance studies. It is concluded that 5-mercapto-6-azauracil is a useful tracer in the investigation of metabolic capacity, as affected by drug therapy, and that it may afford indications concerning the metabolic impairment of the liver.

11850 EFFECTS OF NUCLEIC ACID PRECURSORS ON LIVER INJURIES. II. THE INFLUENCES OF AICA AND AICA OROTATE ON METABOLISMS IN LIVER INJURIES AND THEIR CLINICAL SIGNIFICANCES. (E.) Hashimoto, S. (Western Reserve U., Cleveland, Ohio). J. Vitamin. (Kyoto) 13(1): 19-25, 1967.

Adult male Wistar rats were maintained on a low protein diet for a period of 10 wk. in order to induce liver injuries (fatty liver and slight fibrogenesis); the animals were then divided into 3 groups and were maintained for a period of 4 wk. on a 30% casein diet alone (Group 1, the controls); a control diet supplemented with 0.1% 4-amino-5-imidazole-carboxamide (Group 2) and a control diet supplemented with 0.2% 4-amino-5-imidazole-carboxamide orotate (Group 3). In Group 1, the urinary acetone body and pyruvate, and liver neutral lipid and hexosamine, contents were rapidly restored, while urinary α-ketoglutarate increased after showing an initial tendency to decrease. The iodine numbers of liver phospholipid and neutral lipid, and liver collagen content, did not show any improvement. In Group 3, decrease of the urinary hydroxybutyrate was more marked than in the control, and iodine number of liver neutral lipid increased rapidly; decrease of liver collagen was prompt. Iodine number of the liver phospholipid decreased, and urinary keto acids showed a transient higher level than in the controls. In Group 2, the liver collagen level decreased slightly and iodine number of liver lipid was markedly low; decrease of urinary acetone body and keto acids was more retarded than in the controls. In summary, addition of sufficient amounts of 4-amino-5-imidazole-carboxamide orotate to a high protein diet may prompt recovery of liver injuries induced by a low-protein diet; in view of the equilibrium between purine and pyrimidine in nucleic acid metabolism, 4-amino-5-imidazole-carboxamide is useful. In addition, 4-amino-5-imidazole-carboxamide was admin. to 6 patients with chronic hepatitis and 3 with liver cirrhosis; 4-amino-5-imidazole-carboxamide orotate was given to 1 patient with acute hepatitis (in convalescence), 12 patients with chronic hepatitis, 6 with liver cirrhosis and 2 with Banti's syndrome. Both agents were admin. p.o. for 1-5 mo. in doses of 0.6 g/day divided into 3 portions after meals. In the 4-amino-5-imidazole-carboxamide-treated group, approx. half of the patients showed alleviation of subjective symptoms, diminution of swelling of the liver, decrease of urinary urobilinogen excretion and improvement of BSP clearance; in some there was improvement of serum protein fraction and Kunkel values. In the 4-amino-5-imidazole-carboxamide-orotate-treated group, alleviation of subjective symptoms and swelling of the liver were not evident, but the urinary urobilinogen excretion decreased markedly, and BSP clearance and Kunkel value improved in approx. half the patients. Improvement of serum icterus index and serum protein fractions and elevation in choline esterase activity were noted in 33% of the patients. Improvement after 4-amino-5-imidazole-carboxamide orotate was more pronounced in patients with chronic hepatitis than in those with liver cirrhosis.

11851 EFFECTS OF L-ASPARAGINE AND RELATED COMPOUNDS ON THE HEPATIC FATTY INFILTRATION AND NECROSIS INDUCED BY ETHIONINE AND CARBON TETRACHLORIDE.

(E.) Alexander, N. M. (Yale U. Sch. Med., New Haven, Conn.), R. Scheig and G. Klatskin. Biochem. Pharmacol. 16(6): 1091-1097, 1967.

Female Sprague-Dawley rats were given either DL-ethionine (100 mg/100 g, admin. either by i.p. inj. in 2-5 doses or by gastric intubation as a single dose) or CCl_4, admin. s.c. in a total dose of 0.20 or 0.26 ml/100 g in 2 equal doses 2 hr. apart. The protective effect of L-asparagine (at total dose levels ranging from 80-400 mg) and of other amino acids was studied. I.p. inj. DL-ethionine produced a 2-5-fold increase in hepatic triglycerides within 5 hr. which persisted for at least 24 hr.; ethionine admin. p.o. was equally effective in raising the hepatic triglyceride level. L-Asparagine prevented fatty infiltration of the liver induced by i.p. ethionine, but L-asparagine alone had no effect on hepatic triglyceride conc. Also, L-glutamine, glycine and L-methionine were protective in effect, but L-aspartic acid, L-lysine L-threonine and α-ketoglutaric acid afforded no protection against ethionine-induced fatty infiltration of the liver. Within 5 hr. after s.c. admin. of CCl_4 there was a 2.5-fold increas in hepatic triglycerides; this effect was prevented by i.p. inj. of L-asparagine, L-glutamine L-glutamic acid or DL-methionine, but not by i.p inj. of L-aspartic acid or glycine. L-Asparagin did not prevent CCl_4-induced hepatic necrosis. Chromatographic analysis of the hepatic lipids after CCl_4 admin. revealed that the i.p. inj. of L-asparagine had prevented the expected alterations in the fatty acid pattern indicative of lipid mobilization from adipose tissue.

11852 UPTAKE OF Zn^{65} BY RAT LIVER DAMAGED BY CCl_4.

(E.) Saldeen, T. (U. Lund Sweden) and U. Stenram. Frankfurt. Z. Path. 77(1):61-66, 1967.

The uptake of ^{65}Zn was increased in the liver of Sprague-Dawley rats which had received i.p. 0.02 ml of CCl_4 2 days before the inj. of the Zn. When the Zn was admin. as the chloride it was absorbed from the site of inj. much slower than if given as the citrate. One hr. following the inj. of the radioactive Zn the citrate product showed a marked increase in activity, whereas it was not until 24 hr. later that this increase was seen with $ZnCl_2$. No difference was found in either group 4 days after the inj. Autoradiography showed that the increase in uptake of Zn occurred in the damaged, centro-acinic parts of the liver. When 1 ml of 1% trypan blue soln. was inj. i.v. 3 hr. prior to the s.c. inj. of 0.2 ml of ^{65}Zn citrate in CCl_4-treated rats it had no effect on the uptake of Zn by the liver which supports the assumption that ^{65}Zn-uptake occurs at least mainly in the cells of the liver parenchyma and not in the Kupffer cells.

11853 EFFECT OF ENVIRONMENTAL TEMPERATURE ON FATTY LIVERS PRODUCED BY VARIOUS HEPATOTOXIC AGENTS IN RATS.

(E.) Radomski, M. W. (Defence Res. Med. Lab., Toronto, Canada) and T. Orme. J. Nutr. 92(1):19-22, 1967.

Wistar rats of both sexes were divided into 4 groups of 10-14 rats for each hepatotoxic agent

ted: control and treated groups at each of
2 environmental temperatures tested, 22° and
they were housed at these 2 temperatures for
days before treatment and provided with food
water *ad libitum*. Three experimental diets
the following compositions were used: 1)
t A: 15% vitamin-free casein; 0% soy protein;
corn oil; 0% lard; 71% sucrose; 2.8% non-
ritive fiber; 4% salt mix; and 2.2% vitamin
plement; 2) Diet B, 20%, 0%, 10%, 0%, 61%,
%, 4% and 2.2%, resp.; and 3) 10%, 10%, 0%,
, 51%, 2.8%, 4% and 2.2%, resp. Rats given
ionine and orotic acid were fed Diet A, and
other groups received Diet B; choline
iciency was produced by feeding the rats
t C. Orotic acid at the level of 1% of the
t was admin. to the female rats for 14 days,
the other hepatotoxic agents were given to
rats after 14 days on the experiment. The
lowing dosages and routes of admin. for the
er agents were used: CCl_4 in mineral oil
l vol./vol.), 0.5 ml of mixture/100 g/female,
stomach tube; thionine, 25 mg/ml of water,
mg/female, i.p., 5 times 12 hr. apart; 4-
nopyrazolopyrimidine, 10 mg/ml of water,
g/100 g/male, i.p., 2 times 24 hr. apart, and
anol, 50%, 1.2 ml/100 g/female by stomach tube.
pective control groups at both temperatures
eived equal dosages of the solvent used for
h agent. Fatty liver was produced by each of
treatments in the rats housed at 22°. A
perature of 4° prevented the development of
ty liver in the rats fed the choline-deficient
t in confirmation of previous results, but
no effect on fatty livers caused by the admin.
CCl_4, ethionine, 4-aminopyrazolopyrimidine
orotic acid. Cold exposure significantly
mented the degree of fatty infiltration of the
er produced by 4-aminopyrazolopyrimidine. A
tial lipotropic effect of cold exposure was
rved in rats treated with ethanol.

4 LIVER FUNCTION: POSTPRANDIAL UREA
NITROGEN ELEVATION AND INDOCYANINE
N CLEARANCE IN THE DOG. (E.) Vogin, E. E.
ck Sharp & Dohme Res. Lab., West Point, Pa.),
. Skeggs, D. L. Bokelman and P. A. Mattis.
c. Appl. Pharmacol. 10(3):577-585, 1967.

thod for evaluation of liver function, based
the postprandial elevation of urea N in the
m of beagle dogs of both sexes, is described.
sy specimens were obtained, and alkaline
phatase, SGOT and indocyanine green clearance
er i.v. admin. of 0.5 or 1.0 mg/kg) also
determined after the induction of liver
ry by CCl_4 (2 ml/kg in 2 ml/kg of mineral
admin. by gavage for 2 successive days) or
onine (25 mg/kg, admin. p.o. once a day, 5
/wk., for 4 wk.). The postprandial elevation
rea N was significantly reduced by both
totoxic agents. In ethionine-treated animals
depression of postprandial urea N elevation
the most effective of the clinical diagnostic
s, indicating the onset of hepatotoxicity.
ver, indocyanine green clearance was the most satisfactory test for determining residual hepatic damage during recovery studies after CCl_4 admin. These studies demonstrate that urea N levels of serum increase in response to protein intake in the beagle, and that either rapid (CCl_4) or slow (ethionine) induction of liver damage can be assessed by measurement of the reduction in postprandial rise of serum urea N.

11855 FLUOROMETRIC DETERMINATION OF FREE AND CONJUGATED BROMSULPHALEIN (BSP) IN EXPERIMENTAL LIVER INJURY. (E.) Rodriguez Garay, E. (Nat. Inst. Health, Haedo, Argentina), V. Pérez and M. Royer. *Acta Physiol. Lat. Amer.* 17(1):68-75, 1967.

A sensitive method for the detection of BSP conjugates is described, based on the red fluorescence which BSP spots show under light after being separated by paper chromatography and treated with a 5% KOH ethanol soln. This technic allows the determination of the presence of quantities of BSP as minute as 0.1 µg. Small quantities of material may also be used, a practical advantage in working with laboratory animals. An additional advantage is avoidance of the loss of dye which occurs when it is eluted from the chromatogram. This technic is particularly useful for the determination of serum conjugates, the proportions of which are not as elevated as in bile. In preliminary studies, determinations of BSP fractions by the fluorometric method and by spectrophotometric titration of the eluted spots were in agreement. In contrast, when small samples were used, or when conjugated BSP fractions were not elevated, determinations of their proportions after elution were not particularly accurate.

11856 EFFECT OF ETHIONINE ON THE ULTRASTRUCTURE OF DEVELOPING LIVER CELLS. (E.) Wood, R. L. (U. Minnesota Med. Sch., Minneapolis). *J. Ultrastruct. Res.* 19(1-2): 100-115, 1967.

Fetal livers from pregnant rats (7) and control rats (5) were evaluated for the possible effects of ethionine (dissolved in 0.9% NaCl and inj. i.p.) on the developing fine structure of liver cells and for possible premature and/or abnormal ductal proliferation. DL-ethionine was admin. in dosages of 7.5, 15 and 25 mg/100 g body wt. at 12 or 14 days after mating. Fetal livers were removed and examined at 16, 17, 18 and 20 days by both light and electron microscopy. Normal sequences of developmental changes were observed in the fine structure of hepatocytes in control rats. In the livers of fetuses of rats fed ethionine, the mitochondria granules showed enlargement for all dosages. The lowest dosage (7.5 mg) showed the smallest increase in granule size. With respect to the endoplasmic reticulum, the lowest dosage resulted in no disruption, whereas moderate disruption was noted for both the 15 mg and 25 mg dosages (dose initiated on the fourteenth day). Pronounced disruption of the endoplasmic reticulum was observed for the 25 mg dosage initiated on the twelth day. Lipid deposition was increased for all dosages, being greatly increased for the 25 mg dose started on the twelth day. There was a slight increase in lipid deposition for the 7.5 mg dose. There was no effect on glycogen deposition by the 7.5 and 15 mg doses. Delay in glucogen deposition for both groups of rats fed 25 mg doses [twelfth and fourteenth day initiation times]. No evidence of ductal proliferation was observed.

11857 HEPATIC BLOOD FLOW DURING DIFFERENT DEPTHS OF HALOTHANE ANAESTHESIA IN THE DOG. (E.) Ahlgren, I. (Allmanna Hosp., Malmo, Sweden), K.-F. Aronsen, B. Ericsson and A. Fajgelj. Acta Anaesth. Scand. 11(2):91-96, 1967.

The hepatic blood flow during different depths of halothane anesthesia in the dog was estimated with a new method, based on the disappearance rate of ^{133}Xe (60-80 μc dissolved in saline) inj. into the portal vein; the method makes possible frequent measurement of changes in hepatic blood flow and also allows continual recording of the pressure in the portal vein. Admin. of halothane sufficient to give deep anesthesia was associated with a pronounced fall in hepatic blood flow. With adequate alveolar ventilation, with small changes in arterial CO_2 tension, and no hypoxia, the decrease in hepatic blood flow was parallel to the decrease in cardiac output. If the CO_2 tension in the arterial blood was allowed to rise during deep halothane anesthesia, this was associated with an even more pronounced decrease of hepatic blood flow. It was also noted in these dogs that if the depth of anesthesia was kept constant, an i.v. inj. of 0.25 mg atropine was associated with a pronounced fall in hepatic blood flow.

11858 CHANGES OF LIVER PARENCHYMAL CELLS FOLLOWING PARTIAL HEPATECTOMY WITH SIMULTANEOUS ADMINISTRATION OF ACTINOMYCIN. (Ger.) David, H. (Humboldt U., Berlin) and I. Uerlings. Acta Biol. Med. German. 18(2): 275-290, 1967.

A partial hepatectomy (55-65%) was performed on 22 white rats. Some of the rats received 0.1-1.0 μg/g body wt. of actinomycin C or D, i.p. or intrasplenic at operation or shortly thereafter. The liver was excised 4-31 hr. after surgery and tissue was prepared for electron microscopy (2000-30,000 magnification). Within 24 hr. the resected livers had regained their normal wt. and no gross differences were noted between actinomycin-treated and untreated livers. Untreated livers in the first hr. after operation showed: enlarged nuclei; flocculant karyoplasm; some clumped nucleoli, later hypertrophied and some located adjacent to the nuclear membrane; dilated and partly vacuolated endoplasmic reticulum; ribosome formation, first laid down as polysomes; mitochondria of normal size and structure at 10 hr.; osmiophilic lipid particles in vesicles under the cell membrane; hyperplastic Golgi field and dilated Golgi vesicles containing osmiophilic granules. All these early effects became normal at 24 hr. except for the mitochondria, which, normal at 10 hr., became swollen and rounded with a flocculant matrix. Livers treated with actinomycin showed much more pronounced effects: karyoplasm clotte and detached from the nuclear membrane; clotting or dissociation of nucleoli; formation of vesicles in the endoplasmic reticulum; polysomes partly detached from the membranes; mitochondria swollen, the matrix detached, and the cristae fractured; Golgi fields very hyperplastic with numerous osmiophilic fat particles in vesicles; numerous fat globules in the cells; the striking presence of large numbers of lysosomes close to the Golgi field and to the biliary capillaries. The increased need of RNA and protein syntheses during regeneration was upset by the actinomyci induced disorders of the metabolism of these substances. A single dose of actinomycin does not seem to cause irreversible damage to liver cells.

11859 ALPHA-TOCOPHEROL, CEROID, AND CIRRHOSIS. (E.) Patek, A. J. (Columbia U., New York, N. Y.), F. E. Kendall, N. M. deFritsch and R. L. Hirsch. Arch. Path. (Chicago) 84(3):295-299, 1967.

Ceroid formation which was abundant in the livers of young Wistar rats fed cirrhosis-produ ing diets containing 4% casein, 10% corn oil and 81.5% starch was neither retarded nor prevented by supplements with DL-α-tocopherol (0.5-2 mg/10 g of diet which amounted to 0.9-2.4 mg/day). The food intake and growth rate of animals were suboptimal on this 4% casein diet; the addition of α-tocopherol made no apparent difference in growth rate. All animals showed fatty changes in the livers at 2 mo.; fibrosis and cirrhosis were evident at autopsy at 5 mo. However, there was no apparen correlation between ceroid formation and the amount of fat or fibrosis in the liver. There was a sharp rise in triglycerides and cholester while phospholipid values were roughly half tha of the control rats. The fact that supplements of tocopherol failed to alter ceroid formation was attributed to the high conc. of polyunsaturated fat in the diet (linoleic acid). It appears that ceroid formation plays a secondary role, if any, in the pathogenesis of this type of experimental cirrhosis.

11879 RESULTS OF CORTICOSTEROID TREATMENT OF VIRAL HEPATITIS. (Pol.) Wysocki, J. (1st Infect. Dis. Clin., Warsaw). Pol. Tyg. Lek. 22(27):1035-1038, 1967.

In 651 patients and 151 follow-up cases who were divided into 2 groups (276 treated, 335 controls), the clinical and biochemical results were analyzed. Patients with tuberculosis, diabetes, blood disorders and pregnant women were excluded from this study. Each group was subdivided according to disease severity (6 mg% serum bilirubin - mild, 6-12 mg% medium-severe, over 12 mg% - severe) and age (4-18, 19-60 and over 60 yr.). Treatment most often consisted of an initial dose of 30 mg%/day of cortisone which was gradually reduced every 3 days; in a few cases dexamethasone was used. In the treated group jaundice persisted for a longer period of time (in the under 18 and over 60 yr. age group and in mild cases of the 19-60 yr. age group). Corticosteroid therapy often prolonged the time of hospitalization; however, it increased the appetite and the feeling of well-being and caused a rapid disappearance of dyspeptic and pseudorheumatic symptoms. In the dosage used it caused no severe side effects. Treatment with corticosteroids also seemed to prevent transition of acute viral hepatitis into the chronic form. Follow-up studies 2, 3, 4-7 yr. after illness showed fewer cases of liver enlargement and fewer abnormal liver function tests (especially choline esterase) among those patients treated with steroids during the acute phase of illness. It is concluded that the use of corticosteroids is indicated in viral hepatitis with persisting dyspeptic and pseudorheumatic symptoms, high, long-lasting hyperbilirubinemia, precomatose and comatose states and cases with persistently high levels of serum enzymes.

11880 THE EFFECT OF CORTICOSTEROIDS ON SERUM ALKALINE PHOSPHATASE LEVEL IN PATIENTS WITH VIRUS HEPATITIS. (Pol.) Wysocki, J. (1st Infect. Dis. Clin., Warsaw). Wiad. Lek. 20(5): 475-478, 1967.

Of 343 patients with viral hepatitis 167 were treated with corticosteroids and 176 were control patients. Each of these groups was subdivided according to age (4-18, 19-60, and above 60 yr. old) and severity of disease (light-to 6 mg% of serum bilirubin, medium 6-12 mg% and severe above 12 mg%). Patients received 30 mg cortisone (Erikorton) daily. This dose was then reduced every 3 days. There was no statistically significant difference in the mean values of the alkaline phosphatase levels between the corticosteroid-treated and non-treated patients. In those 19-60 yr. old, a slightly higher enzyme activity was observed in the corticosteroid-treated patients of the mild or medium-severe disease groups. A decrease of bilirubin was often, although not always, accompanied by a decrease of serum alkaline phosphatase activity in patients with viral hepatitis. It is suggested that a decreased activity of this enzyme in the serum of patient with viral hepatitis during a still high serum bilirubin level could be used in prognosis as a sign of an imminent decrease of the bilirubin level and the regression of jaundice.

11881 HEPATITIS AND PREGNANCY. (Ger.) Kallai, L. (U. Zagreb, Yugoslavia), J. Gaon and F. Pinjo. Wien. Z. Inn. Med. 48(5) 186-195, 1967.

Among 3628 pregnant women, 45 cases (1.24%) of hepatitis were found in a 5-yr. period, an incidence similar to that in the general populati These cases were all mild or moderate without fatality. A somewhat greater incidence in the later mo. of pregnancy might have been due to virus inoculation. A circumscribed region (Bos with 200,000 inhabitants was the site of a hepa titis epidemic in 1963; reaching its peak in 19 (241 cases/10,000 population), the epidemic beg a gradual decrease. In 1964 more than 5000 cas of hepatitis were discovered; by August, 1965 1500 more cases were found. All these patients had frank jaundice; if those with anicteric hep titis had been included, the frequency would have been much greater. The frequency of hepatitis during the epidemic was about the same for both sexes; however, almost 10 times as man women died as men (110 women, 13 men). Of the 123 dying during the epidemic, 111 were 16-40 y old and 66 were 20-30 yr. old. The Serbian and Croatian ethnic groups had about the same incidence of hepatitis; the Mohammedans, however, had a greatly elevated incidence amounting to 418 cases/10,000 population; mortality was especially high (119 of the 123 total deaths due to hepatitis). In the course of the epidemic the mortality among pregnant women was 6.2% as compared to the general mortality of women (2.4 Of 19 pregnant women with hepatitis during the epidemic, 4 (21%) died of the disease. Analysi of 218 hepatitis cases during pregnancy showed that 149 recovered and 69 died; mortality was 31.8% and occurred chiefly during the last hal of pregnancy. It is suggested that a high-pro diet, with fewer carbohydrates, especially dur the latter half of pregnancy, might reduce mor

11882 BLOOD COPPER CONTENT OF PREGNANT WOMEN SUFFERING FROM EPIDEMIC HEPATI (Rus.) Shamsutdinova, D. F. (Samarkand Pavlov Med. Inst., USSR). Akush. Ginek. (Moskva) 43(43-47, 1967.

Study of 26 pregnant (26-40 wk.) women with vi hepatitis (mild form, 6; moderately-severe, 15 severe, 5; prodromal periods of different variants) showed that Cu content in the blood (fr the ulnar vein) was higher than in the blood o 25 healthy pregnant women. Cu level was direc proportional to the severity of the disease co Blood Cu content increases mainly due to its

rease in the serum. In patients with mild
m Cu content (in µg%) at increase of symptoms,
the peak of disease and at disappearance of
ptoms was, resp.: in whole blood 185, 152.2 and
.6; in serum 137.6, 115.0 and 103.8; in regular
ments 43.8, 36.8 and 41.0; distribution co-
icient (between regular elements and serum)
1, 0.31 and 0.39. In the patients with moder-
ly severe form it was, resp.: in whole blood
.2, 195.5 and 177.0; in serum 171.5, 151.7 and
.0; in regular elements 52.9, 43.6 and 52.3;
tribution coefficient 0.31, 0.28 and 0.39. In
ents with the severe form it was, resp., in
le blood 234.0, 206.0 and 220.2; in serum 196.0,
0 and 180.5; in regular elements 39.5, 34.0
39.5; distribution coefficient 0.22, 0.19 and
. In healthy pregnant women it was in whole
od 174.0, in serum 115.0, in regular elements
, while the distribution coefficient was 0.47.
ontent in the blood of pregnant patients was
higher than in those who were not pregnant
the distribution coefficient was also more
nsively disturbed. In pregnant patients as
nancy proceeds, Cu content in whole blood,
m and regular elements all increase, while
distribution coefficient decreases. The
severe the course of the disease the more
ounced the decrease in distribution coeffi-
t and the slower its increase. This could
e as an additional test for determining
rity of the disease and its prognosis.

3 ANALYSIS OF SEQUELAE OF VIRAL HEPATITIS
IN PREGNANCY ON THE BASIS OF FOLLOW-UP
INATIONS. (Pol.) Małłek, D. (Strusia
cipal Hosp., Poznan, Poland). Przegl. Epidem.
):199-207, 1967.

een January, 1956 and July, 1964, 149 cases
iral hepatitis among pregnant women were ob-
ed. In only 25% of the cases the course was
um-severe requiring more than 3 wk. of hos-
lization with a bilirubin value of over 10 mg%.
ical and biochemical (blood bilirubin, thymol
, serum protein levels and fractions) follow-
tudies were performed on 62 women divided into
oups: Group 1 (22 cases) was examined several
s 6 mo.-3 yr. after onset of the disease,
2 (40 women) was examined once 3-8 yr. after
disease. Among women of Group 1 75% had
-hepatitis syndrome 3 mo. after the disease
subjective complaints of liver pain in spite
decrease in liver enlargement. There was
a decrease of bilirubin level and thymol
es in spite of continuing pregnancy. The
istence of pregnancy and viral hepatitis
ed to affect serum protein fractions and pro-
levels. There was a decrease of protein
ls and significant hypoalbuminemia which only
ly returned to normal after delivery. Albumin
es still differed from the norm 1 yr. after
very. In Group 2, 37% had no sequelae to
hepatitis in pregnancy, 37.5% complained of
uent pain in the vicinity of the liver and
ed slight deviation of biochemical values,
cially slight dysproteinemia. There was 1
case of severe dysproteinemia and positive thymol test, 3 patients (7.5%) had slightly enlarged livers. Chronic inflammation of other organs was present in 10 women (25% of cases). Two case histories of recurrent, prolonged viral hepatitis were presented but cirrhosis or progressive chronic hepatitis was not noticed in this series of follow-up studies.

11884 EVALUATION OF THE EFFECTIVENESS OF PRESEASONAL ADMINISTRATION OF GAMMA GLOBULIN IN VIRAL HEPATITIS. (Pol.) Kulesza, A. (Inst. Epidem., Warsaw), M. Kacprzak, A. Koźmińska, M. Krajewska, T. Rodkiewicz, L. Twardowska, K. Wagner and H. Waluszkiewicz. Przegl. Epidem. 21(2):215-220, 1967.

Children between the ages of 7-14 yr. were divided into 2 groups: In Group 1, 10,880 children received 0.03 ml/kg of γ-globulin preseasonally at the beginning of September, 1965; Group 2 served as control and consisted of 11,033 pupils who received γ-globulin only when their exposure to viral hepatitis patients was established. The internal structure of both groups as to sex, age, previous incidence of viral hepatitis, family size (number of siblings) was statistically analyzed and proven to be comparable with each other and the general population. Between September, 1965 and August 31, 1966 there were 7 cases of viral hepatitis among the 10,880 children who received γ-globulin preseasonally (64.3 incidence/100,000). These 1-yr. results showed that the percentage of protected children in the experimental group was 90.5% and the index of effectiveness of preseasonal γ-globulin admin. was 1:10.6. While the incidence of viral hepatitis among the control group showed the usual seasonal peak from October through December there was only a sporadic incidence during the entire yr. among the γ-globulin-treated children. It is concluded that preseasonal γ-globulin is more effective against viral hepatitis than it is in just those who are known to have been exposed to the disease.

11885 THE ACTION OF GLUCURONOLACTONE ON THE COMPARATIVE EXCRETION OF 17-KETOSTEROIDS AND GLUCURONIC ACID IN INFECTIOUS HEPATITIS. (Ger.) Buşilă, V. T. (Med. Inst., Timisoara, Rumania), M. Dragomirescu, L. Dragomirescu, A. Rădulescu and A. Zimmer. Z. Ges. Inn. Med. 22(14):426-429, 1967.

These tests were made on 8 normal subjects and 23 hepatitis patients with diagnoses by clinical and laboratory findings. The spontaneous excretion of 17-ketosteroids, the 17-hydroxycorticosteroids as well as glucuronic acid were determined in the 24-hr. urine collection; the next day 0.5 g of glucuronolactone was admin. and the following day, the 3 substances were again determined in the 24-hr. urine collection. The 8 normal subjects, because of the integrity of the liver cells, had a high degree (90%) of utilization of the glucuronolactone and a diminished excretion of glucuronic acid with decreased excretion of 17-ketosteroids (12.60 mg/day before and 9.36 mg/day after admin. of glucuronolactone) and not much change in 17-hydroxycorticosteroid excretion (7.59 mg/day before and 7.80 mg/day after). The av. excretion of those with hepatitis (utilization of the lactone from 81% down to 15%, av. 53%, depending on the severity of the disease) was 17-ketosteroids (9.52 mg/day before and 11.75 mg/day after) and 17-hydroxycorticosteroids (6.74 mg/day before and 9.33 mg/day after).

11886 PROGNOSIS OF VIRAL HEPATITIS. (Ger.) Seifert, E. (Hanusch Hosp., Vienna), H. Dittrich and I. Hölbel. Gastroenterologia (Basel) 107(5):294-304, 1967.

Liver biopsies were taken from 194 patients during the acute phase of viral hepatitis; in 63 there were indications of severe hepatitis, especially in respect to the mesenchymal reaction and in 131 cases the histology showed a light-to-moderate type. These 2 groups were compared after half, 1, 2, and 3 yr. and those with the more severe histological courses showed a longer clinical recovery than those with less liver damage; these differences were statistically significant. Of the group with severe histological indications 7.9% died as compared to 0.8% of the other group. Incidence of cirrhosis in the former group was 14.3% and in the latter 4.6%, chronic hepatitis occurred in 6.3% and 0.8%, resp.; bilirubinemia was the same in both groups: 3.1-3.2%. Therapeutic measures including prednisolone were disappointing; thus, after 3 yr., clinical normality was only 86.2% in 160 cases receiving prednisolone and 95.2% in 172 cases without it in a total number of 332 patients undergoing periodic serum enzyme, bilirubin, liver function tests, and biopsies.

11887 MORPHOGENESIS OF EOSINOPHILIC NECROSIS IN SINGLE PARENCHYMAL CELLS OF THE HUMAN LIVER. CORRELATION OF LIGHT AND ELECTRON MICROSCOPE STUDIES. (Ger.) Moppert, J. (U. Freiburg i. Br., Germany), D. v. Ekesparre and L. Bianchi. Virchow Arch. Path. Anat. 342(3):210-220, 1967.

Liver biopsies of patients with viral hepatitis were studied by light and electron microscopy for the acidophilic necrotic alterations in single cells representing various developmental stages of cytoplasmic coagulation necrosis. The first effect observed under light microscopy was the eosinophilic degeneration of liver epithelial cells; the cytoplasm appeared to be condensed and strongly eosinophilic, the nucleus homogenized and dark; cell boundaries were mostly concave. Ultramicroscopy also showed a condensation of the cytoplasm with close-packing of organelles. Wavy inner and outer membranes surrounded the nucleus, the contents homogenized with no visible chromatin structure. The intensity of the nuclear changes lagged behind those in the cytoplasm. However, the organelles of the cytoplasm were often unchanged. The parenchymal cells had swollen mitochondria with clarification and flocculation of the matrix; vesiculation of the ergastoplasm was noted. Subsequently the necrotic changes took 1 of 2 general courses: 1) The ultrastructure remained fairly constant often with a finely-vacuolated cytoplasm. Cristae and grana of the mitochondria were often lacking. Other minor change in the cytoplasm were observed. The nucleus was pyknotic. 2) The ultrastructure underwent far-reaching changes: In the optical microscope the cells showed acidophil, red or hyaline bodies (Councilman-like bodies) mostly round, sharply-defined, strongly eosinophil, bearing punctate o ribbon-like dark structures. These cells seldom presented a pyknotic nucleus. The cells having taken either course broke up quickly and the fragments, ingested by histiocytes, were digeste or were transformed into eosinophil bodies which disintegrated.

11888 STUDIES ON THE ETIOLOGY OF VIRAL HEPATITIS. III. NEW METHODS FOR ISOLATING VIRUSES FROM THE BLOOD OF PATIENTS WIT VIRAL HEPATITIS. (E.) Georgiades, J. (Dept. Me Microbiol., Cracow, Poland), I. Zgórniak-Nowosie ska, M. Zembala, W. Kilarski and S. Obal. Acta Med. Pol. 8(2):137-156, 1967.

After infecting human thyroid cells with sera obtained 2-16 days after the appearance of jaun from patients (ages 5-75 yr.) with viral hepati plaques appeared in about 12-16 days with diame not exceeding 2 mm. Trials to isolate the cytopathogenic agents by this plaque technic were m with 64 materials from 40 patients by inoculati each material in native form and simultaneously after neomycin and trypsin treatment (for dissoc tion of the virus-inhibitor complex). The smal number of culture results was obtained from nat sera (approx. 20% as compared to approx. 80%), while the difference in the isolation rate from material treated with neomycin or trypsin was slight. Isolation from blood clot homogenates gave somewhat better results than from sera. U sera and performing the test over a 3-mo. perio a high rate of reproducibility of isolations wa obtained. Thirteen of 14 of these isolated vir strains which had previously been passed 3-4 ti in test tube cultures of human embryonic cells were found to be sensitive to 5-iododeoxyuridin and resistant to ether, indicating that these isolated agents belong to the DNA-group of viru Electron-microscopic study of cells infected wi the isolated factors revealed profound changes cellular structure and groups of osmophilic bod 25-50 millimicrons in diameter, sometimes formi large conglomerates.

11889 STUDIES ON THE ETIOLOGY OF VIRAL HEPATITIS. IV. ATTEMPTS OF ISOLATIN VIRUSES ON HUMAN EMBRYONIC FIBROBLAST TISSUE.

giades, J. (Dept. Med. Microbiol., Cracow,
nd), M. Zembala, I. Zgorniak-Nowosielska and
bal. Acta Med. Pol. 8(2):157-162, 1967.

technic previously described allowed the iso-
on of viruses from the sera of patients with
l hepatitis on embryonic fibroblasts. The
ation rate from heated sera was significantly
er than from unheated sera; only inhibitor
ls from myxoviruses were decreased after 6 hr.
ing at 37°. Inhibitor titers for the polyoma
s were not lowered. Sera stored in the freezer
a lower isolation rate. Storage of the sera
°C for several days also decreased the number
solations. Inhibitor levels were not decreased
era kept in the refrigerator before heating.
ty-four strains were isolated, all but 7 pro-
d cytopathic effects after 2-9 passages were
. None were inhibited by ether. Infectious
rs determined by means of cytopathic effect
10^4-10^5. Electron microscope studies re-
ed bodies about 70 millimicrons in diameter
an electron-dense center. The isolated
ins did not agglutinate chicken, sheep or
ea pig RBC. Lack of serologic response demon-
ble by means of the complement fixation test
ne sera of these patients may be evidence that
solated viruses are not related to the disease,
ng their etiologic role to be explained.

APLASIA OF THE BONE MARROW AND VIRUS
HEPATITIS. (Pol.)(Rev.) Kolodziejska,

25 EVIDENCE FOR THE PRESENCE IN HUMAN
PLASMA OF AN ESTROGEN-BINDING FACTOR
ER THAN ALBUMIN: ABNORMAL BINDING OF ESTRADIOL
MEN WITH HEPATIC CIRRHOSIS. (E.) Tavernetti,
T. (Columbia U. Coll. Physicians & Surg.,
York City), W. Rosenbaum, W. G. Kelly, N. P.
isty and M. S. Roginsky. J. Clin. Endocr.
7):920-926, 1967.

binding of estradiol in diluted plasma of
mal men (29), normal women (13) and 26 male
ients with liver cirrhosis was determined
er conditions of equilibrium dialysis at 4°C.
18 of 26 cirrhotics, diagnosis was confirmed
liver biopsy; 2 of these 18 had schistosomal
rhosis, and the remainder had Laennec's
rhosis. Under these conditions, the percentage
free estradiol in the plasma of the normal
(29.0%) was greater than that in the plasma
both the normal women (17.6%) and the
rhotic subjects (20.8%). The normal subjects
normal conc. of albumin in their plasma,
reas the cirrhotic subjects had a lower conc.
observed differences in the binding of
radiol could not be correlated with these
ferences in albumin conc.; therefore the
stence of an additional estrogen-binding fac-
in plasma was postulated. No evident cor-
ation between the binding of estradiol and
degree of feminization of cirrhotics was
nd, and there was no evidence of a correlation
ween the fraction of free estradiol in the
sma of women and the stage of their menstrual
les.

26 PARADOXICAL EFFECTS OF PREDNISONE ON
GLUCOSE METABOLISM IN CIRRHOSIS OF THE
ER. (E.) Radó, J. P. (Janos Hosp., Budapest),
Somogyi, T. Takó and G. Bikich. Z. Vitamin
non Fermentforsch. 14(4):343-355, 1967.

20 patients with liver cirrhosis, 8 had
anced, decompensated cirrhosis with severe
ites and 12 had compensated cirrhosis. The
ients were fed a carbohydrate-rich preparatory
for several days before the study. A total
40 mg of prednisone was admin. daily for 5-7
, and this short-term treatment was followed
an acute prednisone-loading (30 mg at 6 a.m.,
ng at 7 a.m., followed by ingestion of glucose).
id i.v. and standard glucose tolerance tests
e made repeatedly and during the standard
, arteriovenous glucose difference was deter-
ed. The relative assimilation index was
culated according to Somogyi, and was regarded
an index of peripheral glucose utilization.
adoxical changes in glucose metabolism were
erved after admin. of prednisone. The
appearance rate of glucose increased in most
the patients in response to short-term treat-
. An increase of intrahepatic utilization
suggested, since in response to the same
atment, peripheral glucose utilization
erally decreased. The relative assimilation index increased in the compensated group during acute loading only, indicating a relative increase in the peripheral glucose utilization. The standard blood sugar curve became flatter during short-term treatment in the decompensated group, and in some cases the peripheral glucose utilization also improved.

11927 PLASMA UNESTERIFIED FATTY ACIDS AND LIPOPROTEIN LIPASE ACTIVITY IN CIRRHOSIS OF THE LIVER. (Pol.) Ignatowska, H. (2nd Intern. Dis. Clin., Warsaw) and T. Wąsowska-Ciszek. Pol. Arch. Med. Wewnet. 38(3): 309-314, 1967.

Plasma unesterified fatty acids, lipoprotein lipase activity (at rest and after heparin admin.) were determined in 34 patients (39-71 yr. old) with cirrhosis and compared to values obtained from 14 healthy subjects (22-35 yr. old). In 9 patients the lipoprotein lipase level in the peripheral vein was compared to that in the hepatic venous blood which was obtained by catheterization of the hepatic vein. The level of unesterified fatty acids varied in patients with cirrhosis between 0.393 mEq/liter and 3.036 mEq/liter. The mean value of 1.190 mEq/liter ± 0.661 was higher than that of the controls (0.526 mEq/liter) and the difference was statistically significant. There was no statistically significant correlation between the unesterified fatty acid level and the albumin level. Neither controls nor patients with cirrhosis showed serum lipoprotein lipase activity without previous heparin admin. Lipase activity after heparin admin. varied after 1 hr. incubation between 5.6 U and 35.4 U. The mean value of 18.2 ± 10 was lower than that found in the control subject but the difference was statistically insignificant. During the second hr. of incubation there was a significantly greater increase of enzyme activity in patients with cirrhosis than in the controls. In the controls the increase of activity varied between 39-76% (av. 57% ± 14) compared to the first hr. of incubation while in the patients it varied 46-176% (av. 110% ± 42). The difference was statistically valid. After heparin admin. no difference of lipoprotein lipase activity could be found between samples of peripheral blood and blood from the hepatic vein in patients with cirrhosis of the liver.

11928 INTESTINAL ABSORPTION IN CIRRHOSIS OF THE LIVER. (Pol.) Bogdał, J. (2nd Intern. Dis. Clin., Cracow), K. Cichecka, H. Drożdż, A. Jędrychowski, S. Kirchmayer and M. Mysik. Pol. Arch. Med. Wewnet. 38(3): 283-291, 1967.

A diet containing 100 g of fat was given to patients with cirrhosis of the liver for 5 days and after the third day fats in the stool were determined. The patients were divided into 2 groups; the first group (11) had portal hypertension and ascites, the second group (6) cirrhosis without ascites. A non-steatorrheic weak-to-moderate diarrhea was present in 4 patients of the first group and 1 of the second. Determination of fats in the stools showed a definite increase of total fats, neutral fats and fatty acids in 5 of the first group. Among patients of the second group there was no increase of fats above normal levels. Analysis of neutral fat, fatty acids and the quantitative ratio of the 2 components with a demonstration of a relationship between lipid absorption and portal congestion indicated that impaired utilization of fat in cirrhosis of the liver is due to both disturbed digestion and abnormal intestinal absorption. Only a minor degree of fat absorption impairment could be noted (mainly after fat loading) and in the majority of cases diarrhea did not result. Diarrhea was more common in patients who showed no malabsorption. The vitamin A level increase after loading was inhibited in 13 of 17 patients tested and the weaker increase of vitamin A level was more pronounced in patients of the first group. Serum carotene levels were decreased in 5 patients, nounced in patients of the first group. Serum carotene levels were decreased in 5 patients, serum vitamin A levels were decreased in 7 patients and did not correlate with the results of fat determination in stools. The D-xylose test showed a reduced urinary excretion of pentose in 9 patients of the first group and 3 of the second group but did not correlate with the results of the fat-loading tests. There was no correlation between the results of the fat-loading test and the BSP test, bilirubin level, transaminase activity, choline esterase level, prothrombin complex and serum albumin.

11929 CULTIVATION OF PERIPHERAL LEUCOCYTES IN THE PRESENCE OF LIVER ANTIGEN IN LIVER CIRRHOSIS.

(E.) Hoenig, V. (Ist Dept. Intern. Med., Prague) and V. Pössnerová. Z. Immunitaetsforsch. 133(2):199-204, 1967.

Peripheral WBC from 7 patients (1 man, 6 women) with liver cirrhosis and from 5 blood donors were cultivated with and without human liver antigen. The WBC were isolated and cultivated according to the technic of Hungerford in Quaglino's modification, using Epl's medium instead of TC 199. The differential count in cultures from cirrhotic patients was very variable, particularly with regard to polynuclear WBC and macrophages. The proportion of transition cells or of blastoid elements did not exceed 2% both with and without liver antigen added. In cultures from 3 patients with cirrhosis rare mitoses were present on the third day of cultivation with liver antigen, in 1 of them repeatedly. Mitoses did not occur in WBC cultures from cirrhotic patients without liver antigen added or in control cultures. Control cultures with phytohemagglutinin revealed a typical stimulation consisting of a striking increase of transformed elements and mitoses. These results indicate that there are no striking quantitative differences between the culture of WBC from cirrhotic and normal subjects. If autoimmunization were implicated, a more pronounced stimulation would have been expected in the presence of liver antigen; the slightly increased stimulation of WBC cultures from some cirrhotic patients by liver antigen requires further study.

11930 ANALYSIS OF THE CONDITIONS FOR THE APPEARANCE OF ANTIBODIES DURING HEPATIC CIRRHOSIS.

(Fr.) Rochant, H. (Cent. Dept. Blood Transfusion, Paris), A. Gerbal, A. Najman, D. Salmon, F. Grémy, C. Salmon and J. Caroli. Nouv. Rev. Franc. Hemat. 7(3):415-425, 1967.

Patients with liver cirrhosis (60 men and 29 women) were examined for immune antibodies. Each received 15 different tests including 5 different anti-RBC, auto-antibody, iso-antibody and hemagglutinin tests; single antiplatelet, anti-WBC and antinucleoprotein tests; antiglobulin and antithyroidoglobulin; anticardiolip and heterophil antibody tests as well as tests for antibodies against specific blood groups. A large group of subjects with normal livers also underwent these tests showing that concomitant with cirrhosis there is a derangement of the antibody-forming system reacting in an exaggerated way to the stimulus of transfusion. Auto-agglutination of RBC, very rare among normal individuals, occurred in 32% of cirrhotics. Antinuclear antibodies were present in 45% of cirrhotics as compared to 8% of those with normal livers. There was an absence of iso-antibodies, immune anti-RBC, anti-WBC and anti-platelets in individuals with liver cirrhosis. The 89 cirrhotics also had elevated rheumatoid factors (18%), nonspecific antiglobulin (12%) and nonspecific heterophil antibodies (40%); the effects were more pronounced among the women. Although many possible factors (such as portal hypertension) were considered in analysis of the test data, no definite explanation of the antibody reactions of cirrhosis was found.

11931 SECRETION OF GASTRIC ACID AFTER ADMINISTRATION OF HISTALOG AND GASTRIN PENTAPEPTIDE IN PERSONS WITH HEALTHY LIVERS AND PATIENTS SUFFERING FROM LIVER CIRRHOSIS.

(Ger.) Adlunge, J. (Ist Med. Clin., Lubeck, Germany), E. Schmid and G. Junker. Z. Gastroent. 5(4): 218-221, 1967.

The stimulation of gastric acid secretion by 50 mg betazole and by 0.25 mg gastrin pentapeptide admin. s.c. was compared in separate tests given to 20 subjects, 10 normal and 10 wi liver cirrhosis. Gastric secretion was collecte in 10-min. fractions for 1 hr. and in 15-min. fractions in the next hr. after removal of resting secretion. Acid was determined in the

ctions by titration. In effect, 0.25 mg of
trin was about equal to 50 mg of betazole,
ching about the same peak acid value in 45-60
. Stimulation of acid secretion by betazole
ved longer persistence, having a value of
ut 40 mEq HCl/liter after 2 hr. as compared
3 mEq/liter for stimulation by gastrin.
nulation of gastric acid secretion in cirrhotic
ients showed higher peak values than normal
longer persistence for both compounds, with
of betazole being greater after 2 hr.
tazole 45 mEq/liter and gastrin 35 mEq/liter).

32 CIRRHOSIS OF THE LIVER, ALCOHOLISM AND HEAVY SMOKING ASSOCIATED WITH CANCER
THE MOUTH AND PHARYNX. (E.) Keller, A. Z.
Cent. Office, Washington, D. C.). Cancer
5):1015-1022, 1967.

ew York City study of cancer of the mouth and
rynx is presented, based on 408 cases and 408
-matched controls; each case was a male with
tologically-confirmed squamous cell carcinoma
the mouth or pharynx. The median age was 60
, and distribution among other age groups was
follows: 30-39 yr., 2.2%; 40-49 yr., 18.1%;
59 yr., 26.7%; 60-69 yr., 41.2%; 70-79 yr.,
, and 80 or more yr., 2.0%. Clinically
gnosed liver cirrhosis was found in 20% of the
es and 9% of the controls, a statistically
nificant difference. An excess of liver
rhosis was significant for cases of cancer of
floor of the mouth, uvula and soft palate,
pharynx and hypopharynx. Among 28 cases of
existing carcinoma, liver cirrhosis was found
4.3% of them and in 7.2% of their age-matched
rols. A total of 42% of the cases were
y drinkers (1.6 or more ounces of liquor/day),
ared to 19% of the controls; excess of heavy
king among cases was significant for cases
carcinoma of the floor of the mouth and meso-
ynx (as with cirrhosis) and tongue. Heavy
ing was found among 26% of the cases, and
of the controls; excess of heavy smoking was
ificant for cases of carcinoma of the floor
he mouth (as with cirrhosis) and tongue. For
airs matched by age and use of alcohol, the
entage with clinically diagnosed cirrhosis of
liver was 22% among the cases and 11% among
controls. Cirrhosis of the liver occurred
early 33% of the patients and controls who
k excessively, but it occurred in only 13%
56 patients and 3% of 190 controls who did
drink heavily. The association of liver
hosis with cancer was even found to exist
patients as cases and controls consumed the
amount of alcohol. The association of
hosis with cancer also existed when patients
ases and controls smoked the same amount of
cco. Heavy smoking was not associated with
hosis of the liver. These findings are
istent with the conclusion that heavy smok-
heavy drinking and liver cirrhosis (either
e or as a measure of heavy drinking) are
ciated with cancer of the mouth and pharynx.

11933 MITOCHONDRIAL ANTIBODIES IN PRIMARY BILIARY CIRRHOSIS. I. LOCALIZATION OF THE ANTIGEN TO MITOCHONDRIAL MEMBRANES. (E.) Berg, P. A. (Middlesex Hosp. Med. Sch., London), D. Doniach and I. M. Roitt. J. Exp. Med. 126(2): 277-290, 1967.

Sera from 34 patients with proven primary biliary cirrhosis were evaluated by quantitative complement fixation and immunofluorescence studies in order to attempt localization of the antigen. Complement fixation antigen was recovered in the crude mitochondrial fraction in the greatest amount (50-75%) with the rest being recovered from the nuclear fraction and the 26,000 times gravity fluffy layer. Mitochondrial samples generally contained 2000-3000 U/ml. All 34 sera samples reacted strongly with mitochondrial fractions when tested by quantitative complement fixation. The mitochondrial location of the antigen was confirmed by the use of marker enzymes. Using succinic dehydrogenase as a mitochondrial marker, a high correlation for complement fixation activity in the mitochondrial fraction was obtained. To exclude lysosomal involvement in the complement fixation reaction, complement fixation and marker enzyme studies were conducted on lysosomal fractions. No appreciable antigenic activity was demonstrated. Staining patterns using the direct conjugate of IgG from 1 patient with primary biliary cirrhosis paralleled those obtained by histochemical assay for succinic dehydrogenase. Staining was most intense in those cells with mitochondria and intact cristae. Separate studies in which the mitochondria were fragmented by hypotonic soln., hexane (solvent), lysolecithin (detergent), and ultrasound further demonstrated that the antigen involved in primary biliary cirrhosis is associated with the mitochondrial inner membranes.

11934 ALBUMIN SYNTHESIS RATE AS A MEASURE OF LIVER FUNCTION IN PATIENTS WITH CIRRHOSIS. (E.) Hasch, E. (Bispebjerg Hosp., Copenhagen), S. Jarnum and N. Tygstrup. Acta Med. Scand. 182(1):83-92, 1967.

A total of 21 patients (7 men, 14 women; 46-78 yr. old, with a mean of 64 yr.) with cirrhosis of the liver (confirmed histologically in 18) and 28 control subjects were studied with ^{131}I-labeled human albumin. Three cirrhotic subjects were studied before and after prednisone treatment (approx. 20 mg/day). Turnover data of the 2 groups were compared, and in the group with cirrhosis, the data were compared with the results of common liver function tests and the clinical severity of the disease. A highly significant difference existed between several parameters of albumin turnover in the 2 groups. Albumin synthesis rate showed the most pronounced reduction in patients with cirrhosis as compared with control subjects (approx. 50%); the serum albumin conc. was only depressed to 61% of the normal mean. Albumin clearance and fractional catabolic rate were only slightly depressed in cirrhotics. Only plasma vol. was higher than normal in cirrhotics. In the 3 patients treated with prednisone, albumin synthesis rates increased in all, as did the clinical condition, and the serum albumin increased in 2. Within the group with cirrhosis, statistical treatment of the data showed that albumin synthesis rate was poorly and insignificantly related to other liver function tests. It is concluded that albumin synthesis rate as determined by radioiodine-labeled albumin is an unreliable measure of the severity of cirrhosis, and like most other liver function tests, it is uncertain as a prognostic guide in the individual patient.

11935 REGRESSION OF DIETARY CIRRHOSIS IN RATS FED ALCOHOL AND A "SUPER DIET." EVIDENCE OF THE NONHEPATOTOXIC NATURE OF ETHANOL.

(E.) Takada, A. (Hosp. Sick Child., Toronto, Canada), E. A. Porta and W. S. Hartroft. Amer. J. Clin. Nutr. 20(3):213-225, 1967.

Male albino Wistar rats were maintained for 7 mo. on a solid semisynthetic food mixture low in protein, choline and vitamin B_{12}. At the start of the eighth mo., the rats were distributed among 3 groups according to the severity of hepatic injury ascertained at laparotomy: Group 1 was used as an untreated negative control by continuing its members on the solid, basal, choline-deficient diet; Group 2 received an alcohol-containing liquid diet; and Group 3 received a nonalcohol liquid diet. Each liquid diet provided 1.0 calories/ml. In the alcoholic diet, 36% of the total calories was provided by alcohol; 15.36% by carbohydrates; 25.60% by fat; and 23.04% by protein. In the nonalcoholic diet (the "super diet"), 24% of total calories derived from sucrose, 40% from fat, and 36% from protein. All 3 groups were fed their respective diets for 3 mo. Mortality rates in Groups 1, 2, and 3 were 33%; 20% and 33%, resp. Rats in Group 1 grew poorly, attaining finally a total increase of only 15% of their initial wt.; rats in Groups 2 and 3 increased almost 40% in their av. body wt. The values of liver wt. in Group 1 were higher than those in Groups 2 and 3, with no significant differences between the last 2 groups. Rapid and remarkable improvement of all measured parameters of liver function was observed in Groups 2 and 3. SGOT and alkaline phosphatase activities were higher, and albumin:globulin ratios and total cholesterol were lower, in Group 1 than in Groups 2 and 3; no significant differences were found among the latter, with the exception of values of serum total cholesterol which, at the end of the experiment, were significantly higher in Group 2 animals. Hepatic DNA content was significantly higher in Group 1 than in Groups 2 and 3, with no differences among the latter. No significant differences in content of hepatic RNA were found in any of the groups. The content of dry defatted tissue (corresponding to the content of crude protein in the liver) were significantly lower in Group 1 than in Groups 2 and 3. Group 1 had a significantly higher content of alkali-soluble collagen than Groups 2 and 3. Hepatic triglycerides in Group 1 were approx. 10-fold higher than in Groups 2 and 3. High levels of total cholesterol were found in livers of Group 1, while in the other 2 groups, particularly 2, these values were significantly lower. The highest levels of hepatic phospholipids were Group 2; however, the differences between these values and those of Group 1 were only slightly significant and did not differ in significance from those of Group 3. At the end of the experiment, livers of rats from Group displayed lesions that conformed to the fatty multilobular type of cirrhosis; in livers from rats of Group 2, visible fat had almost disappeared, nodules were considerably smaller, and trabeculae thinner and relatively acellular; ceroid had become quite prominent; livers of Group 3 rats resembled those of Group 2, except that ceroid was even more prominent. Under the electron microscope, hepatocytes of rats from Group 1 showed the most severe ultrastructural changes; mitochondria in general were enlarged (megamitochondria) and spherulated with diminuti and shortening of their cristae; ribosomes were diminished and usually dispersed; hepatocellular cytoplasm was vacuolated by dilatation of the cisternae of the endoplasmic reticulum. Configuration of hepatocytes in Group 2 was better preserved, with only minor abnormalities demonstrated. The general impression was that mitochondria were better preserved in Group 3 hepatocytes than in those of Group 2. It is concluded that addition of alcohol to the nutritionally adequate "super" diets permitted regression of cirrhosis to the same degree as in comparably cirrhotic animals given the same diets without the added alcohol. This result provides evidence against the hypothesis that alcohol is cirrhogenic by virtue of a direct hepatotoxic action.

11936 LIVER AND SERUM ZINC ABNORMALITIES IN RATS WITH CIRRHOSIS.

(E.) Kahn, A. M (Wadsworth Hosp., Los Angeles, Calif.) and R. S. Ozeran. Gastroenterology 53(2):193-197, 1967.

Alterations of Zn metabolism found in rats with hepatic cirrhosis induced by i.p. inj. of 10% CCl_4 in olive oil 5 times/wk. for 10 wk. were so similar to those described in man that this albino rat preparation may provide a laboratory model for further study of Zn in the physiopatho of liver disease. The mean liver-Zn conc. of the normal rats was 29.6 µg/g (wet wt.) whereas the mean of the cirrhotic group was 25.3. The mean serum Zn conc. of the normal rats was 152.7 µg/100 ml and that of the cirrhotic rats was 128.8 µg/100 ml. In 17 cirrhotic rats the mean albumin was 2.8 g/100 ml and the globulin was 3.6 g/100 ml. The mean serum albumin and globulin of the normal rats were 3.2 g/100 ml an 3.9 g/100 ml, resp. Statistically, all these differences were significant; however, no correlation was found between the liver and seru conc. or between the serum proteins and the ver or serum Zn levels.

11948 EXAMINATION OF SACCHARIDE AND GLYCOPROTEIN CONTENT IN GALLSTONES. (Ger.) Józsa, L. (Bacs-Kiskun Hosp., Kecskemet, Hungary), G. Szederkényi and B. Góg. Z. Ges. Inn. Med. 22(12):368-371, 1967.

Gallstones obtained at autopsy were analyzed for their major components and for glucose, galactose-mannose, hexosamine, sialinic acid, ascorbic acid, fucose, protein, and mucoproteins. The ash content of the stones was also determined and varied from 0.5% in cholesterol stones to 79% in the limestone type; pigment stones had 1.7% ash; the other types (combinations in varying proportions of these basic types) had intermediate ash contents. Glucose was demonstrated in all stones but the greatest amount was in pigment stones (between 24 and 522 mg%) and the least in the limestones (12-60 mg%). Galactose-mannose showed great variations but, on the av., followed the distribution of glucose. Hexosamine could be demonstrated in only half the stones; the greatest amount in cholesterol and cholesterol-lime stones with ranges from 40-240 mg%. Sialinic acid was present in 96% of the stones analyzed; the greatest conc. of this acid was found in the pigment stones (126-708 mg%) and the least in the limestones (45-135%). Ascorbic acid was found in only half the stones; this compound was seldom found in the pigment stones; it varied from 84-750 mg% in limestones and was relatively less in combination stones. Fucose was found in 30 of 100 stones. In every case pigment stones contained fucose but the distribution and amount were quite variable. Protein occurred in 90% of stones from 0.4-5.5 g% in the various types; the amount varied with relatively greater conc. in the small stones. All stones had mucoproteins; they were in greatest conc. in the pigment stones and least in limestones. The content of protein and mucoprotein was largest in the center of the stones and decreased toward the periphery. Proteins and mucoproteins seem to play a part as an agglutinant in the formation of the nucleus of the stone.

11949 DIET-INDUCED CHOLESTEROL GALLSTONES IN HAMSTERS: PREVENTION AND DISSOLUTION BY CHOLESTYRAMINE. (E.) Bergman, F. (U. Umeå, Sweden) and W. van der Linden. Gastroenterology 53(3):418-421, 1967.

A total of 60 young Syrian hamsters of both sexes were divided in a strictly random fashion into 2 equal groups. Group 1, the control group, was fed a gallstone-inducing diet (glucose, 74.3%; casein 20.0%; salt mixture, 5.0%; vitamin mixture, 0.5%; and choline chloride, 0.2%). Group 2, the test group, was given the same diet with the addition of 3% cholestyramine. The number of cholesterol, mixed and pigmented stones, and no stones, in 25 animals of Group 1 was 18, 4, 1 and 2, resp., while in Group 2 (27 animals) it was 0, 0, 8 and 19. The 18 animals in Group 1 that developed cholesterol gallstones were continued on the gallstone-inducing diet supplemented with 3% cholestyramine; in 2 mo. cholesterol gallstones disappeared in 10 of 16 animals. No influence on amorphous stones was found. Of animals surviving treatment during a third mo., cholesterol gallstones were still present in 2. Histologically, livers appeared normal in all groups and no signs of fatty degeneration were found. Since amorphous pigmented stones were unaffected by cholestyramine, it is concluded that the cholesterol stones had disappeared by dissolution.

11950 TREATMENT OF REMAINING BILE DUCT CALCULI. (Pol.) Dadan, H. (2nd Surg. Clin., Bialystok, Poland), T. Jankowski, A. Dowgird and Z. Korfel. Pol. Tyg. Lek. 22(34):1286-1289, 1967.

Since gallstones can be dissolved by a mixture of 75% chloroform and 25% rapeseed oil at a temp. of 38°, this method was used to treat 5 patients with residual stones after surgery. Every 2 days approx. 2 ml of the mixture was introduced into the bile duct (through Kehr's drain in 4 cases, through a gallbladder fistula in 1 case); the mixture was kept in the duct for approx. 35 min. and the procedure was repeated 4-8 times. When a long-lasting constriction of Oddi's sphincter was necessary, 2-3 tablets of 0.02 codeine phosphoran were given p.o. or 0.01 morphine was inj. before introducing the chloroform mixture. A 1% soln. of lidocaine (Xylocaine) was used to anesthetize the bile duct when patients complained of pain following introduction of the mixture. The remnants of dissolved calculi were washed out by introducing every 2 days through Kehr's drain, a physiologic saline soln. (approx. 500 ml at 30 cm H_2O pressure) which was warmed to body temperature. This method of treatment was used on 5 patients with good results in every case; all symptoms disappeared in these patients and no side effects were observed. Follow-up studies revealed a good general condition and no complaint concerning the bile ducts. This procedure is recommended where bile duct concretions are overlooked during surgery and eliminates the need for a second operation. However it has no application in cases of organic constriction of these ducts.

11951 CORONARY ATHEROSCLEROSIS AND CHOLELITHIASIS. (Pol.) Domaniewski, J. (City Hosp., Bydgoszcz, Poland), E. Terziman and G. Domaniewska. Pol. Tyg. Lek. 22(19):704-706, 1967.

The frequency of coexisting coronary atherosclerosis and gallstones was determined and statisticall analyzed on 2550 autopsies. These consisted of 555 cases of cholelithiasis and 1995 controls. The specimens were divided into 5 groups according to severity of atherosclerotic changes and 8 age groups of patients (from 20 to over 90 yr. old). There were 3 times as many cases without coronary theromatosis in the control groups than among hose with cholelithiasis. The atherosclerotic hanges were classified as severe in over 50% of he patients with gallbladder disease (as com- ared to 33% of the controls), appeared at a ounger age and were independent of sex. These ifferences were statistically significant.

1952 Rh FACTOR AND ABO BLOOD GROUPS IN PATIENTS WITH CHOLECYSTITIS. (Pol.) Korfel, Z. 2nd Surg. Clin., Bialystok, Poland), P. Podsiadły nd L. Ostrowski. Pol. Tyg. Lek. 22(10):339-341, 967.

e results of a statistical analysis of ABO blood oups and Rh factor distributions among 912 pa- ents (151 men, 761 women) with cholecystitis d 5372 healthy subjects (3095 men, 2277 women) e presented. Only patients whose diagnosis of olecystitis was confirmed by microscopic exam- ation after surgery and only people living in e same general area were included. Statistically gnificant differences were found in the dis- ibution of A and O blood groups. There was a re frequent occurrence of blood group A among tients with cholecystitis (46.4% of men, 47.0% women) when compared to healthy subjects (37.0% men, 37.2% of women) while there was a less equent occurrence of blood Group O among chole- stitis patients (23.2% of men, 28.0% of women) an among the control group (36.7% of men, 36.1% women). There were only slight, statistically significant differences in the distribution of e Rh factor and B and AB blood groups. It is ggested that people belonging to blood group O e less susceptible to cholecystitis while those longing to blood group A have a greater chance developing this disease than other people.

953 RECTAL CHOLECYSTOGRAPHY. (E.) Sargent, E. N. (Orange County Gen. Hosp., Calif.), H. Guth and M. Graffman. Radiology 88(5): 7-1001, 1967.

e effectiveness of sodium ipodate and calcium odate as cholecystographic contrast media, ctally admin., is reported in 43 patients (25 le and 18 female subjects aged 30-80 yr.) with- t demonstrable hepatobiliary disease. In those patients who retained the medium, 22 (58%) nonstrated visualization of the gallbladder ich was considered diagnostically adequate (60% th the Na salt and 57% with the Ca salt). sualization was considered better than the ical oral cholecystogram in 18 (47%) patients. sualization to some degree was obtained in a tal of 87% of the patients. A high percentage those receiving the Na salt experienced dif- culty in enema retention. Most patients demon- rated an adequate visualization of the gall- adder within 6 hr., while 4, 2 and 1 patient quired 8, 10 and 12 hr. resp., for biliary vis- ization. Retrograde flow of the contrast medium not correlate with the quality of the chole- togram. There was no significant liver or kidney toxicity as well as other observed side effects. This procedure is recommended as a substitute for oral cholecystography when the latter procedure is not feasible.

11954 ON THE TECHNIQUE OF CHOLECYSTECTOMY AND CHOLEDOCHOSTOMY. (E.) Seiro, V. (U. Helsinki) and K. Kettunen. Acta Chir. Scand. 133(4):320-322, 1967.

There are 2 conventional technics of cholecystectomy; in 1, the cystic artery and cystic duct are ligated before the gallbladder is freed, beginning from the cystic duct; in the second, removal of the gallbladder is begun from the fundus and the cystic duct and cystic artery are not ligated until the final stage. A new technic of cholecystectomy is described in which sharp dissection of the gallbladder is begun at the fundus and continued to the neck; the organ is displaced laterally, and by palpating the hepatoduodenal ligament between the fingers the anatomy of the vessel of the liver is established and any vascular anomalies are localized; peritoneum of the ligament is incised and the anterior wall of the common bile duct and of the hepatic duct, as well as of the cystic duct, are exposed; the cystic artery is ligated after identification, and not until after its ligation is the cystic duct severed. The gallbladder fossa and hepatoduodenal ligament are left unsutured; drainage is always applied to the operative field. A new choledochostomy technic is also described, using a needle technic. A thin inj. needle is inserted through the anterior wall of the common bile duct; by raising the needle ventrally, the anterior wall of the common bile duct and incision is made along the needle. Both of these technics have been used successfully with minimal complications in a large teaching hospital in which most of the (500) bile duct operations done annually are performed by resident surgeons.

11955 STRICTURE OF THE GALL BLADDER. (E.) Beilby, J. O. W. (Middlesex Hosp., London). J. Path. Bact. 93(1):175-184, 1967.

Study of 40 gallbladder strictures in adults and 1 in a 10-yr.-old child revealed that all of them contained muscle. In an examination of 72 neonates, 11 basically similar strictures were found. The sex ratio in both adult and neonatal groups was 3 females to 1 male. Strictures seen in adults were considered to be congenital in origin. From a study of 3 human embryos, it appeared likely that such strictures arose by incomplete vacuolization of the solid embryonic gallbladder bud. The gallbladder wall distal to adult strictures usually showed epithelial sinus and crypt formation with muscular hypertrophy, progressing to "cholecystitis glandularis proliferans", where the stricture is narrow. Such changes were never observed in infants or neonates. The gallbladder wall changes appeared to result from raised intracystic tension, and to be best regarded as a form of diverticulosis. The association of "cholecystitis glandularis proliferans" with strictures of narrow lumen, the strict localization to the wall distal to the obstruction, the muscular hypertrophy and the flattened epithelium lining the crypts were all indicative of an obstructive etiology, possibly coupled with raised intracystic pressure.

11956 BILIRUBIN ENCEPHALOPATHY IN THE GUNN RAT: A FINE STRUCTURE STUDY OF THE CEREBELLAR CORTEX.

(E.) Schutta, H. S. (Pennsylvania Hosp., Philadelphia) and L. Johnson. J. Neuropath. Exp. Neurol. 26(3):377-396, 1967.

Cerebellar pathology, as revealed by both light and electron microscopy, in 55 homozygous rats with experimental jaundice is described with emphasis on the fine structure of the cerebellar cortex, as well as the absence of such pathology in newborn rats, occurrence of cerebellar alteration in rats without clinical manifestations of pathology, and association of cerebellar alteration with serum albumin and bilirubin conc. Localized staining of the basal ganglia and cerebellum was not visible until 24 hr. after birth. The cerebellum was smaller than normal at 10 days postpartum, and the hemispheres consisted of only 2 thin leaves 30 days after birth. In jaundiced rats showing no ataxia, light microscopy revealed only cerebellar abnormality in the Purkinje cells. Atrophied hemispheres, however, revealed diminished cell populations in the granular, molecular and Purkinje layers, as well as a derangement of the lobular pattern of the cerebellum. Employing osmium-fixed sections, abnormalities were noted earlier, with osmiophilic granules and whorled structures being noted in the cytoplasm of some Purkinje cells. Electron microscope analysis revealed abnormalities in the cytoplasm of the Purkinje cells as early as 30 hr. after birth. The incidence of cerebellar abnormality was in direct proportion to the severity of the cerebellar ataxia and abnormalities were observed uniformly in all jaundiced rats over 3 days of age.

11957 BIOPHYSICS OF LIPID ASSOCIATIONS. III. THE QUATERNARY SYSTEMS LECITHIN-BILE SALT-CHOLESTEROL-WATER.

(E.) Bourgès, M. (Pasteur Inst., Paris), D. M. Small and D. G. Dervichian. Biochim. Biophys. Acta 144(2):189-201, 1967.

The amount of cholesterol that can be incorporated into the different aqueous phases, paracrystalline or micellar (isotropic soln.) in the presence of lecithin and bile salt was studied, using the quaternary systems formed with lecithin, bile salt, cholesterol and water. The different phases formed by the quaternary mixtures were studied by both the ordinary and polarizing microscopes, and their paracrystalline molecular structure was determined by X-ray diffraction. A quaternary diagram was employed, representing the composition of the regions of existence of single phases or the equilibrium of the different phases: isotropi micellar soln., paracrystalline lamellar, hexagona and cubic phases. These phases were identical with those obtained with the ternary systems lecithin-bile salt-water. Cholesterol could be incorporated into each of these phases without any important modification in their structure, and no new phase appeared as a consequence of this addition of cholesterol. The solubilization of cholesterol obtained by the simultaneous presence of lecithin and bile salt is stressed. Bile was compared to 1 of the quaternary systems examined, and containing 0.5% cholesterol, 85% water, 11.5% bile salt and 3% lecithin. The compositions of normal human (and animal) bile lay within the micellar zone IV, whereas the compositions of bile from patients having cholesterol gallstones was just outside this zone, in the region of 2 phases where cholesterol crystals separate from the micellar phase. Regardless of the mode of growth of cholesterol gallstones, a prerequisite for stone formation is a bile which is oversaturated with cholesterol, i.e., a bile with a composition outside zone IV.

11958 PROBLEMS OF REFLUX INTO PANCREATIC DUCT (WIRSUNG'S DUCT).

(Cz.) Moravec, R. (Fac. Med., Bratislava, Czechoslovakia), J. M. Bencúr and F. Mlček. Cesk. Radiol. 21(4):238-244, 1967.

In more than 300 cases studied by cholangiography during or after surgery, reflux into Wirsung's duct was found in 60 patients (20%). The length of reflux was 0.5-3.0 cm in 22 patients, 3.5-5.0 cm in 18, 5.5-10.0 cm in 10, 10.5-15.0 cm in 3 and 15.5-20.0 cm in 7; width of reflux was 0.5-3.0 mm in 34 patients, 3.5-5.0 mm in 22, 5.5-8.0 mm in 4. Diastases, lipases and Ca values were normal, and the patients were subjectively well. It is the authors' opinion that reflux could be caused by such factors as the anatomy of the biliopancreatic pathways, the action of drugs, the hypertonic condition of the bile duct, high pressure (more than 35-40 cm of H_2O), chronic pancreatitis, position of patient at examination, X-ray technic, frequency and start of radiologica examination, and quantity and conc. of contrast material. One case history is given in some detai

11990 ROENTGEN DIAGNOSIS OF BILIARY TRACT DISEASES. (Rus.) Maksumov, D. N. Tashkent, Meditsina, 1966, 115pp.

11991 CHOLANGIOCHOLECYSTOGRAPHY BY SLOW INFUSION OF THE CONTRAST MEDIUM (D.I.C.) IN ASSOCIATION WITH CIRCULAR TOMOGRAPHY IN THE STUDY OF THE BILE DUCTS. (It.) Algranati, R. (Holy Cross Civil Hosp., Cuneo, Italy) and C. Alberti. Minerva Med. 58(72):3078-3081, 1967.

11992 NEW METHOD OF INVESTIGATION OF BILIARY TRACT: PERFUSION CHOLANGIOCHOLECYSTOGRAPHY. (It.) Ricci, A. (Inst. Holy Spirit, Rome) and A. Guidetti. Nunt. Radiol. 32(10): 1047-1057, 1966.

11993 PERFUSION CHOLANGIOCHOLECYSTOGRAPHY. (It.) Toaiari, E. (Hosp. Inst., Verona, Italy) and S. Gavala. Quad. Radiol. 32(3): 505-522, 1967.

11994 COMPARATIVE STUDY OF THE ADVANTAGES OF HYPOTONIC DUODENOGRAPHY WITH RESPECT TO "STANDARD" RADIOGRAPHIC EXAMINATION OF PATIENTS IN DIAGNOSIS OF DISEASES OF THE PANCREAS AND PAPILLA OF VATER. (It.) Napolitano, A. (U. Rome), G. Tumino and R. Franceschini. Ann. Ital. Chir. 43(3):399-425, 1966.

11995 CLINICAL TRIAL OF BILIVISTAN, A NEW CONTRAST MEDIUM FOR INTRAVENOUS CHOLECYSTOGRAPHY. (Nor.) Bång, I. Nord. Med. 78(30):970-971, 1967.

11996 PROLONGED PERORAL CHOLECYSTOGRAPHY. (Cz.) Bruna, J. (Inst. Radiol. Med., Kromeriż, Czechoslovakia). Cesk. Radiol. 21(4): 245-249, 1967.

11997 EVALUATION OF THE DIAGNOSTIC VALUE OF ORAL CHOLECYSTOGRAPHY ON THE BASIS OF PERSONAL OBSERVATIONS. (Pol.) Kulicz, A. (Inst. Radiol., Zabrze, Poland). Przegl. Lek. 23(4):390-391, 1967.

11998 USEFULNESS OF INTRADUODENAL CHOLECYSTOGRAPHY IN EXAMINATION OF THE BILE TRACT. (Pol.) Wlazłowski, Z. Pol. Tyg. Lek. 22(35):1330-1332, 1967.

11999 TRANSCUTANEOUS CHOLANGIOGRAPHY AND CHOLANGITIS. (Rus.) Shor, L. M. (Kaliningrad Reg. Hosp., USSR), R. S. Kondratova and S. M. Shikhman. Klin. Med. (Moskva) 45(7): 72-76, 1967.

12000 THE CASE FOR PEROPERATIVE CHOLANGIOGRAPHY. (E.) Griffin, T. F. R. (Scarborough Hosp. Group, England) and A. A. Wild Brit. J. Surg. 54(7):609-615, 1967.

12001 PAPILLO--ODDITIS. HISTOLOGIC STUDY ON BIOPSY MATERIAL. (It.) Nicora, E. (Galliera Hosp., Genoa, Italy). Pathologica 58(867-868):443-464, 1966.

12002 POSTOPERATIVE STUDY OF THE BILIARY TRACT BY TRANSHEPATIC DRAINAGE. (It.) Pomidori, A. (U. Naples, Italy). Fegato 13(1): 86-109, 1967.

  trauma: 11301
  ulcer: 11279*,11284*,11640*
  varices: 11289,11322*,11743*

FAT (see Absorption, lipid; Digestion; Lipids; Liver, metabolism, lipid; Malabsorption)
FECES: 10957*,10981*,11087*,11174,11176,11187, 11188,11197,11425,11426,11543*,11546*,11676*
FISTULA (see under individual organs)

GALLBLADDER (see also Biliary Tract; Cholecystitis; Cholelithiasis): 11170
  aging: 11967
  anomalies: 11955*,12011,12012
  associated diseases: 11966
  cholecystokinin (see also Pancreas, pancreozymin): 11013*,11031*,11032*,11080,11670*
  clinical studies: 11995
  development: 11955*
  diagnosis
    radiology: 11953*,11961,11991,11992,11993, 11995,11996,11997,11998
      angiography: 11208
  diseases: 11047*,11967,11968,12010
  motility: 11080,11961,11966
  mucosa: 12011
  neoplasms
    malignant: 11220*
  obstruction: 11955*

GALLBLADDER (Contd.)
  surgery: 11013*,11954*,11972,12008,12009,12010
GAS: 11283*,11401*,11669*,11811
GASTRECTOMY (see also Malabsorption; Ulcer, surgery; Stomach, neoplasms, malignant): 11328*,11333*,11379,11394,11487,11671*
  clinical results: 11326*,11327*,11388,11392, 11393,11440*,11442*,11485
  complications: 11391,11395,11679
    dumping syndrome: 11326*,11468
    malabsorption: 11519*,11531
    metabolic changes: 11390,11483,11519*,11706*
    recurrent ulcer: 11493
    treatment: 11326*,11396
  technic: 11325*,11354,11377,11485,12010
GASTRIN (see Stomach, gastrin)
GASTRITIS: 11047*,11318*,11322*,11326*,11360, 11361,11365,11514*
  associated diseases: 11317*,11366
  atrophic: 11037*,11056*,11317*,11366
  pathology: 11362,11363,11364
  treatment: 11170,11341
GASTROENTERITIS (see also Colitis; Enteritis; Enterocolitis): 11226*,11255
GASTROINTESTINAL TRACT (see also specific organs; Cancer)
  anomalies: 11229
  biochem, enzymes: 10933
  biopotentials: 10917*,10956*,10962*,10973*, 10989*,10996,11018*,11077*,11078*
  carcinogenesis: 11866
  children: 10920*,11245,11246,11404*
  circulation: 11302
  clinical studies: 11234
  diagnosis: 11169,11770
    biochemical procedures: 10952*,11176,11177, 11755*
    endoscopy: 11331*
    radiology: 10998,11212,11601,11985
      angiography: 11161*,11302
  diseases: 11165,11169,11173,11231,11233, 11235,11256,11755*,11770
  diverticula(-itis): 11216*
  fistula: 11391,11965
  function: 11468,11601
  hormonal control: 10998
  immunology: 11177
  metabolism: 11046*
  motility: 10923
  neoplasms
    malignant: 11202,11238
  nervous control: 10918*
    psychologic factors: 10920*,11230,11512, 11806
  pathology: 11167,11228*
  polyps: 11013*
  treatment: 11169,11173,11408,11565
    drug: 10934,10966*,11133,11142,11160*, 11162*,11167,11170,11171,11172,11174, 11175,11179,11275,11357,11419,11449*, 11499,11566,11688,11707,11755*,11949*
    hormone: 11159*
    physical: 11504,11505,11506,11507,11598
    surgical: 11166,11236,11237,11250,11251, 11252,11510*,11743*
  water and electrolyte metabolism: 11101*, 11139,11166,11250,11402*,11610,11621,11972

GASTROSCOPY (see Stomach, diagnosis, endoscopy)
GENETIC RELATIONSHIPS: 11123,11215*,11516*,11517* 11528,11676*,11754*,11755*
  blood groups: 11482,11952*
GLUCAGON: 11093*,11103*
GLYCOGEN STORAGE DISEASE: 11754*

HEMOBILIA (see under Biliary Tract)
HEMOCHROMATOSIS: 11720*
HEMORRHAGE (see Bleeding)
HEMORRHOIDS: 11216*,11566
HEPATECTOMY (see Liver, regeneration)
HEPATIC COME (see Liver, coma)
HEPATIC VEIN THROMBOSIS (see Budd-Chiari Syndrome)
HEPATITIS (see also Liver, coma and entries under Liver; Jaundice): 11736*,11801,11896,11899
  acute: 11748*,11850*,11900
  associated diseases: 11800,11890,11892
  children: 11884*
  chronic: 11723*,11729*,11748*,11749*,11798, 11802,11850*,11886*,11959
  clinical studies: 11894
  diagnosis: 11891,11901
    biochemical procedures: 11733*,11882*, 11888*,11924
  epidemiology: 11881*,11897,11898,11904, 11908,11909,11918,11918
  etiology: 11888*,11889*,11905
  experimental studies: 11895
  immunology: 11729*,11799,11903,11922,11923
  toxic (see Liver, injury, toxic agents)
  treatment: 11728*,11836,11850*,11879*,11880*, 11913,11914,11915,11916,11959
  viral: 11644*,11719*,11735*,11737*,11746*, 11750*,11879*,11880*,11881*,11882*,11883*, 11885*,11886*,11887*,11888*,11889*,11890, 11891,11892,11893,11894,11895,11897,11901, 11902,11903,11904,11905,11906,11908,11909, 11910,11912,11913,11914,11915,11916,11917, 11918,11919,11920,11922,11923,11970
    prophylaxis: 11884*,11907,11921
HEPATOLENTICULAR DEGENERATION (WILSON'S DISEASE): 11794,11795
HEPATOMEGALY (see Liver, disease)
HERNIA (see also Diaphragm, rupture): 11200, 11216*,11402*
  diaphragmatic: 11302,11303,11304
  hiatal: 11280*,11284*,11309,11310,11311,11322*
  inguinal: 11245,11246
HIRSCHSPRUNG'S DISEASE (see Megacolon, congenital)
HISTAMINE: 10933,11011*,11012*,11016*,11027*, 11032*,11033*,11034*,11035*,11036*,11037*, 11039*,11041*,11044*,11047*,11048*,11049*, 11054*,11055*,11056*,11147,11170,11323*,11341, 11343,11344,11444*,11450*,11457*,11498
HYPOTHERMIA (see also Bleeding, treatment, cooling; Ulcer, peptic, gastroduodenal, treatment, freezing): 11143,11356,11853*

ICTERUS (see Jaundice)
ILEOCECAL VALVE: 11412
ILEUM (see also Intestine, Small): 10937*,10955* 11412,11517*,11620

  - biochemical procedures: 10944,11037*,11040*,11056*,11059,11213,11318*,11346,11348,11355,11361,11372,11384,11385,11394
  - endoscopy: 11213,11315*,11336,11339,11345,11346,11347,11375,11382,11499
  - gastric analysis: 11024*,11026*,11056*,11328*,11355
  - radiology: 11038*,11209,11210,11211,11334*,11335,11337,11338,11340,11346,11358,11375
    - angiography: 11208

STOMACH (Contd.)
- diseases: 11286,11346,11351,11357,11358,11367,11460,11940
  - mucosal injury: 11324*,11456*
- fistula: 11035*,11036*,11594
- gastrin: 10968*,11028*,11030*,11031*,11032*,11034*,11448*,11931*
- hormonal control: 11017*,11042*,11342
- immunology: 10944,11056*,11319*,11320*,11321*
- intrinsic factor: 11011*,11024*,11056*,11319*
- metabolism: 11029*
- morphology: 10939*,11044*,11320*,11329*,11453*
- motility: 11012*,11070*,11073*,11081,11171,11285*,11349,11441*
- mucosa: 10918*,10922*,10944,11017*,11022*,11029*,11030*,11037*,11056*,11240,11318*,11320*,11321*,11323*,11324*,11334*,11342,11348,11358,11363,11372,11387,11394,11496
- neoplasms
  - benign: 11375
  - malignant: 11047*,11220*,11312*,11313*,11314*,11316*,11317*,11326*,11333*,11367,11368,11369,11370,11372,11373,11374,11376,11377,11378,11379,11380,11381,11382,11383,11384,11385,11386,11387,11452*,11490
  - villous: 11371
- nervous control: 10918*,10943,11054*,11073*,11329*,11352
  - psychologic factors: 11454*
- obstruction: 11300
- pathology: 11058,11345,11360,11369
- perforation: 11380
- perfusion: 11036*,11448*
- polyps: 11317*,11326*
- secretion: 10918*,11057
  - acid: 11011*,11012*,11014*,11016*,11023*,11028*,11031*,11032*,11033*,11034*,11035*,11036*,11037*,11038*,11039*,11041*,11042*,11043*,11044*,11045*,11047*,11048*,11049*,11050*,11051*,11054*,11055*,11056*,11060,11061,11327,11343,11344,11347,11352,11364,11443*,11448*,11467,11931*
  - drug effects: 11011*,11027*,11031*,11032*,11033*,11034*,11035*,11036*,11037*,11039*,11041*,11043*,11044*,11045*,11047*,11048*,11049*,11050*,11051*,11054*,11055*,11056*,11341,11343,11344,11456*,11448*,11931*
  - electrolytes: 11027*,11042*
  - in disease: 11011*,11012*,11037*,11047*,11055*,11056*,11058,11061,11327*,11342,11364,11443*,11467,11487,11931*
  - mucus: 11023*,11054*,11456*
  - neurohumoral control: 11042*,11050*
  - pepsin: 10986*,11028*,11040*,11050*,11063*,11064*,11067,11455*
  - technics of study: 11011*,11012*,11014*,11016*,11023*,11027*,11028*,11031*,11032*,11033*,11034*,11036*,11037*,11038*,11039*,11041*,11042*,11043*,11044*,11045*,11047*,11048*,11051*,11054*,11055*,11059,11060,11327*,11343,11344,11448*
- surgery: 11160*,11298,11388,11493,11679,11680

- STOMACH (Contd.)
  - surgery (Contd.)
    - antrectomy and vagotomy: 11440*,11442*, 11484,11487,11519*
    - gastroenterostomy: 11327*
    - gastroenterostomy and vagotomy: 11441*, 11442*
    - gastrostomy: 11562
    - pyloroplasty and vagotomy: 11354,11441*, 11442*,11484,11519*
    - vagotomy: 11016*,11034*,11035*,11039*, 11061,11070*,11134,11349,11352,11440*, 11483,11485,11486,11489
    - technic: 11330*,11353,11354,11377,11392, 11439*,11485,12010
  - toxic effects
    - chemical: 11324*
  - volvulus: 11359
- SULFOBROMOPHTHALEIN: 11091*,11097*,11734*,11748*, 11749*,11757*,11758*,11772,11773,11774,11849*, 11850*,11855*
- SURGICAL APPARATUS: 11322*,11331*,11397*,11399*

- TRANSPLANTATION (see also Immunology; Liver, transplantation)
- TRYPSIN (see Pancreas, secretion)
- TYPHOID FEVER (see also Salmonellosis)

- ULCER (see also Antacids; Anticholinergics; Duodenum; Gastrectomy; Intestine, Small, ulcer, nonspecific; Ulcerative Colitis)
  - drug-induced: 11450*,11451*,11456*,11457*, 11643*
  - etiology: 11458*
  - experimental: 11049*,11333,11449*,11450*, 11451*,11452*,11453*,11455*,11456*,11457*, 11458*,11643*
  - nonspecific (simple): 11556
  - peptic: 11025*,11322*,11372,11677*
    - aging: 11462,11463
    - associated diseases: 11367,11443*,11466, 11469,11938,12010
    - children: 11465,11475,11477
    - clinical studies: 11443*,11444*
    - complications (see also Pyloric Obstruction): 11396,11492
      - bleeding: 11159*,11443*,11474,11475, 11488
      - perforation: 11439*,11440*,11476,11477, 11478,11479,11480
    - diagnosis: 11445*,11459,11476,11500
      - biochemical procedures: 11317*,11471
      - radiology: 11443*,11472,11473
    - epidemiology: 11446*,11462,11464,11476, 11502,11647*
    - etiology: 11012*,11443*,11446*,11454*, 11461,11482
- ULCER (Contd.)
  - peptic (Contd.)
    - metabolic changes: 11444*,11514*
    - motility: 11012*
    - pathology: 11362,11445*,11470,11471

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from medical journals published throughout the world. In the abstract issues, approximately one-third of the citations dealing with the major aspects of gastroenterology had accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:
